

The Schulze Method of Voting

Markus Schulze

Markus.Schulze@Alumni.TU-Berlin.de

Summary. In recent years, the Pirate Party of Sweden, the Wikimedia Foundation, the Debian project, the Gentoo project, and many other private organizations adopted a new single-winner election method for internal elections and referendums. In this paper, we will introduce this method, demonstrate that it satisfies e.g. resolvability, Condorcet, Schwartz, Smith-IIA, Pareto, reversal symmetry, monotonicity, prudence, and independence of clones and present an $O(C^3)$ algorithm to calculate the winner, where C is the number of alternatives.

Keywords and Phrases: Condorcet criterion, independence of clones, monotonicity, Pareto efficiency, reversal symmetry, composition consistency, single-winner election methods, prudent ranking rules

JEL Classification Number: D71

Summary

In this paper, we will propose a new single-winner election method (section 2). This method will be illustrated on a large number of examples (section 3). We will show that this method satisfies a large number of desirable criteria (section 4), e.g. *resolvability* (section 4.3), *reversal symmetry* (section 4.5), *monotonicity* (section 4.6), *independence of clones* (section 4.7), *prudence* (section 4.10), *k-consistency* (section 4.14), and *composition consistency* (section 5). In those cases, where the proposed method violates a criterion, this will be shown by using concrete counterexamples; see e.g. sections 3.7, 3.8, and 3.9.

In section 4, we use a deterministic model for election methods. In section 5, we will show what we have to take into consideration when we use a probabilistic model instead.

In sections 8 and 9, the proposed method will be generalized to “Proportional Representation by the Single Transferable Vote” (STV) and to methods to calculate a proportional ranking. Sections 8 and 9 differ significantly from the other sections. This is caused by the fact that, while we have the McGarvey method to easily create instances for single-winner elections (McGarvey, 1953), we don’t have a similar method to create instances for multi-winner elections; therefore, large real-life instances are usually used to illustrate STV methods (Tideman, 2000); see section 8.2 of this dissertation. Furthermore, while there is a giant literature on mathematical aspects of single-winner election methods, there are no established criteria for STV methods; however in section 8.3, we will propose generalizations of the Condorcet criterion and the Smith criterion to STV methods.

Symbols

$\wedge$	... and ...
$\vee$	... or ...
$\forall$	... for all ...
$\exists$	... there is at least one ...
$\in$	... element of ...
$\notin$	... not element of ...
$\setminus$	“ $a \in B_1 \setminus B_2$ ” means “ $a \in B_1$ and $a \notin B_2$ ”.
$\cap$	“ $a \in B_1 \cap B_2$ ” means “ $a \in B_1$ and $a \in B_2$ ”.
$\cup$	“ $a \in B_1 \cup B_2$ ” means “ $a \in B_1$ or $a \in B_2$ ”.
$\subseteq$	“ $B_1 \subseteq B_2$ ” means “ B_1 is a subset of B_2 or even identical to B_2 ”.
$\subsetneq, \subset$	“ $B_1 \subsetneq B_2$ ” means “ B_1 is a subset of B_2 , but not identical to B_2 ”.
$\Rightarrow$	... then ...
$\Leftrightarrow$	... then and only then ...
$: \Leftrightarrow$	... by definition then and only then ...
$\succ_v$	“better than” or “greater than” according to v
$\succsim_v$	“better than or equal to” or “greater than or equal to” according to v

$<_v$	“worse than” or “smaller than” according to v
$\lesssim_v$	“worse than or equal to” or “smaller than or equal to” according to v
$\approx_v$	“equal to” according to v
$:=$	... equal by definition ...
$\times$	a tuple For example: “ $a \in \mathbb{N}_0 \times \mathbb{N}_0$ ” means “ a is an ordered pair of two (not necessarily different) elements of $\mathbb{N}_0$ ”.
A	set of alternatives
A_M	A_M is the set of the $(C!)/((M!)\cdot((C-M)!))$ possible ways to choose M different alternatives from the set A of C alternatives.
C	$C \in \mathbb{N}$ with $0 < M < C < \infty$ is the number of alternatives.
M	$M \in \mathbb{N}$ with $0 < M < C < \infty$ is the number of seats.
$\max_D B$	maximum element in set B according to measure D
$\min_D B$	minimum element in set B according to measure D
N	$N \in \mathbb{N}$ with $0 < N < \infty$ is the number of voters.
$N[a,b]$	$N[a,b] \in \mathbb{N}$ with $0 \leq N[a,b] \leq N$ is the number of voters who prefer alternative $a \in A$ to alternative $b \in A \setminus \{a\}$.
$N[\{a_1, \dots, a_M\}; b]$	$N[\{a_1, \dots, a_M\}; b] \in \mathbb{R}_{\geq 0}$ with $0 \leq N[\{a_1, \dots, a_M\}; b] \leq N / M$ is the largest value such that each alternative in $\{a_1, \dots, a_M\} \subset A$ has a separate quota of this value against alternative $b \in A \setminus \{a_1, \dots, a_M\}$.
$\mathbb{N}$	natural numbers without zero, $\mathbb{N} = \{1, 2, 3, \dots\}$
$\mathbb{N}_0$	natural numbers with zero, $\mathbb{N}_0 = \{0, 1, 2, 3, \dots\}$

O	collective ranking
$\emptyset$	the empty set
$P_D[a,b]$	$P_D[a,b] \in \mathbb{N}_0 \times \mathbb{N}_0$ is the strength of the strongest path from alternative $a \in A$ to alternative $b \in A \setminus \{a\}$ when the strength is measured by D (where D can e.g. be <i>margin</i> , <i>ratio</i> , <i>winning votes</i> or <i>losing votes</i>).
$p[O]$	$p[O] \in \mathbb{R}_{\geq 0}$ with $0 \leq p[O] \leq 1$ is the probability that the binary relation O wins.
$q[a,b]$	$q[a,b] \in \mathbb{R}_{\geq 0}$ with $0 \leq q[a,b] \leq 1$ is the probability that alternative $a \in A$ is ranked above alternative $b \in A \setminus \{a\}$ in the collective ranking.
$r[a]$	$r[a] \in \mathbb{R}_{\geq 0}$ with $0 \leq r[a] \leq 1$ is the probability that alternative $a \in A$ wins.
$\mathbb{R}$	real numbers
$\mathbb{R}_{\geq 0}$	real numbers larger than or equal to zero
S	set of (potential) winners
V	set of voters
$O _B, S _B, q[a,b] _B, r[a] _B$	... when applied only to the alternatives in set B ...
$\ B \ $	number of elements in set B
$\{ a \in B \mid \textit{property} \}$	set of elements of set B with <i>property</i>
$\ \{ a \in B \mid \textit{property} \} \ $	number of elements of set B with <i>property</i>

Abbreviations

DDP	Dummett-Droop proportionality

 DOI	digital object identifier (without open access)
IIA	independence of irrelevant alternatives
MMP	mixed member proportional representation
PRPL	proportional representation by party lists
STV	proportional representation by the single transferable vote
TBRC	tie-breaking ranking of the candidates
TBRL	tie-breaking ranking of the links
TBRV	tie-breaking ranking of the voters

1. Introduction

One important property of a good single-winner election method is that it minimizes the number of “overruled” voters (according to some heuristic). Because of this reason, the Simpson-Kramer MinMax method, that always chooses that alternative whose worst pairwise defeat is the weakest, was very popular over a long time (Simpson, 1969; Kramer, 1977). However, in recent years, the Simpson-Kramer MinMax method has been criticized by many social choice theorists. J.H. Smith (1973) criticizes that this method doesn’t choose from the top-set of alternatives. Tideman (1987) complains that this method is vulnerable to the strategic nomination of a large number of similar alternatives, so-called *clones*. And Saari (1994) rejects this method for violating *reversal symmetry*. A violation of reversal symmetry can lead to strange situations where still the same alternative is chosen when all ballots are reversed, meaning that the same alternative is identified as best one and simultaneously as worst one.

In this paper, we will show that only a slight modification (section 4.9) of the Simpson-Kramer MinMax method is needed so that the resulting method satisfies the criteria proposed by J.H. Smith (section 4.8), Tideman (section 4.7), and Saari (section 4.5). The resulting method will be called *Schulze method*. Random simulations by Wright (2009) confirmed that, in almost 99% of all instances, the Schulze method conforms with the Simpson-Kramer MinMax method (table 11.1). In this paper, we will prove that, nevertheless, the Schulze method still satisfies all important criteria that are also satisfied by the Simpson-Kramer MinMax method, like resolvability (section 4.3), Pareto (section 4.4), monotonicity (section 4.6), and prudence (section 4.10). Because of these reasons, already several private organizations have adopted the Schulze method.

1997 – 2006: In 1997, I proposed the Schulze method to a large number of people, who are interested in mathematical aspects of election methods. This method was discussed for the first time in a public mailing list in 1997/1998 (e.g. Schulze, 1997, 1998a, 1998b, 1998c; Ossipoff, 1998; Petry, 1998), when it was discussed at the *Election-Methods mailing list*. In June 2003, Debian, a software project with about 1,000 members, adopted this method in a referendum with 144 against 16 votes (www001); Debian GNU/Linux is the largest and most popular non-commercial Linux distribution. In May 2005, the Gentoo Foundation, a software project with about 200 members, adopted this method (www002); Gentoo Linux is another wide-spread Linux distribution.

2007 – 2012: In 2008, 2009, and 2011, the Wikimedia Foundation, a non-profit charitable organization with about 43,000 members (in 2011), used the proposed method for the election of its Board of Trustees (www003); the Wikimedia Foundation is the umbrella organization e.g. for Wikipedia, Wiktionary, Wikiquote, Wikidata, Wikibooks, Wikisource, Wikinews, Wikivoyage, Wikiversity, and Wikispecies; in 2011, Wikimedia was the fourth most important Internet corporation (after Alphabet/Google/YouTube, Facebook/WhatsApp/Instagram, and Yahoo!). In July 2008, Ubuntu, a software project with about 700 members, adopted this method (www004). In August 2008, “K Desktop Environment” (KDE), a software project with about 150 members, adopted this method (www005). In October 2009, the “Pirate Party of Sweden” (about 1,800 members) adopted this method

(www006). In November 2009, the “European Democratic Education Community” (EUDEC; about 8,000 members) adopted this method (www007). In May 2010, the “Pirate Party of Germany” (about 6,000 members) adopted this method. In November 2010, OpenStack, a software project with about 3,500 members, adopted this method (www008). Since February 2011, the “Pirate Party of Austria” (about 200 members) uses this method (www009); in 2013, the “Pirate Party of Austria”, the “Communist Party of Austria”, and “The Change” used the proposed method to create a joint list (“A Different Europe”) for the 2014 elections to the European Parliament (www010). Since November 2011, the “Pirate Party of Australia” (about 1,300 members) uses this method (www011). In December 2011, the “Pirate Party of Italy” adopted this method (www012). In July 2012, the “United States Pirate Party” (about 3,000 members) adopted this method (www013).

2013 – 2019: Since January 2013, the “Pirate Party of Iceland” (about 5,000 members) uses this method (www014). Since April 2013, the associated student government at Northwestern University (about 20,000 members; www015) uses this method. Since October 2013, the “Five Star Movement” (“Movimento 5 Stelle”, M5S), a political party in Italy with about 120,000 members, uses this method (www016). In December 2013, the “Club of the Alumni of the German Student Academies” (“Club der Ehemaligen der Deutschen SchülerAkademien”; CdE; about 4,500 members) adopted this method (www017). Since January 2014, the “Pirate Party of Belgium” (about 400 members) uses this method (www018); frequently, the “Pirate Party of Belgium” and the “Volt Party of Belgium” are running with a joint list (“Purple Party of Belgium”) which is then also generated with the proposed method (www019). Since May 2014, the associated student government at Albert Ludwig University of Freiburg (about 25,000 members) uses this method (www020). Since January 2015, the “Pirate Party of the Netherlands” (about 1,800 members) uses this method (www021). In February 2016, the city of Silla (about 19,000 inhabitants) in Spain adopted the Schulze method for referendums (www022; Gómez Álvarez, 2018). In July 2016, the “European Students’ Forum” (“Association des états généraux des étudiants de l’Europe”, AEGEE), a student organization with about 13,000 members, adopted this method (www023). Since January 2017, Podemos, a political party in Spain with about 520,000 members, uses this method (www024). In March 2017, the “Internet Corporation for Assigned Names and Numbers” (ICANN) adopted the Schulze method for the election of its board and the board of the “Address Supporting Organization” (ASO), a supporting organization affiliated with ICANN (www025). In December 2017, the “Associated Students of Minerva Schools at Keck Graduate Institute” (about 1,000 members) adopted the Schulze method (www026). In June 2019, “Volt Europa”, a pan-European political party with about 3,000 members, adopted the Schulze method for internal decisions (www027).

Today (October 2025), the proposed method is used by more than 200 organizations with more than 4,000,000 members in total. Therefore, the proposed method is more wide-spread than all other Condorcet-consistent single-winner election methods combined. This method is also used by Kleros (www028), Knative (www029), Kubernetes (www030), GraphQL

(www031), Dapr (www032), Helm (www033), Hacksburg (www034), Homebrew (www035), StarlingX (www036), Airship (www037), Brigade (www038), NetBSD (www039), PETSc (www040), Ergodis (www041), Squeak (www042), Tekton (www043), Sugar Labs (www044), RLLMUK (www045), FFmpeg (www046), foOpGp (www047), OpenSwitch (www048), OpenEmbedded (www049), DataSHIELD (www050), D-CENT (www051), TestPAC (www052), Ithaca Generator (www053), Fair Trade Northwest (www054), “Gothenburg Hackerspace” (www055), “Olten now!” (“Olten jetzt!”, www056), “Free Geek” (www057), “Board Game Geek” (www058), the “Free Software Foundation Latin America” (FSFLA, www059), the “Open Neural Network Exchange” (ONNX, www060), the “Python Software Foundation” (www061), the “Cloud Foundry Foundation” (www062), the “Cloud Native Computing Foundation” (www063), the “Computational Geometry Society” (www064), the “LIGO Scientific Collaboration” (www065), the “FinOps Foundation” (www066), the Boise, Idaho, section of the Democratic Socialists of America (DSA, www067), the Pirate Party of Portugal (www068), the “Australian Better Families Party” (www069), the Burgerlijst movement in Belgium (www070), the “Democratic Foundation of Austria” (“demokratisches bündnis österreich”; dbö; www071), the “Democracy Centre Vienna” (“Demokratiezentrum Wien”, www072), the Mathematics Department of Tufts University (Merow, 2016; www073), the “Yale Postdoctoral Association” (www074), the “International Union for the Study of Social Insects” (IUSSI; www075), the Mathematics Society of the University of Waterloo (www076), the Math Club at Western University (www077), the University of Michigan Fencing Club (www078), the Open Computing Facility of the University of California at Berkeley (www079), the associated student government at the Catholic University of Leuven (about 58,000 members; www080), the associated student government at the Computer Sciences Department of Kaiserslautern-Landau University of Technology (www081), the Innocenzo Manzetti Institute of Technology at Aosta (www082), the associated student government of the High School of Paris (“délégation générale des élèves de l’école normale supérieure de Paris”; about 2,700 members; www083), the “Canadian Undergraduate Mathematics Conference” (CUMC, www084), the “International Olympiad in Informatics” (www085), and the “Groupe francophone des Utilisateurs de T_EX” (GUT or GUTenberg; Chupin, 2022). It is used by the “Swedish National Union of Students” (“Sveriges förenade studentkårer”; SFS; about 380,000 members; www086), the “Union of Computer Science Students at the Swedish Royal Institute of Technology” (www087), the “Union of Media Technology Students at the Swedish Royal Institute of Technology” (www088), the “Union of Physics and Mathematics Students at the Swedish Royal Institute of Technology” (www089), the “Union of Students of Energy and Environmental Sciences at the Swedish Royal Institute of Technology” (www090), the “Union of Students of Aerospace Engineering at the Swedish Royal Institute of Technology” (www091), the Swedish Tourist Association (“Svenska Turistföreningen”; about 300,000 members; www092), the Swedish Kennel Club (“Svenska Kennelklubben”; SKK; about 300,000 members; www093), the Swedish Society for Nature Conservation (Naturskyddsföreningen; about 230,000 members; www094), the Swedish Trade Union of Public Employees (Vision; about 200,000 members; www095), the Swedish Trade Union for Academics (Akavia; about 135,000 members; www096), the Swedish Association for Nursery and Midwifery (Vårdförbundet; about 114,000 members; www097), the Swedish Union for Service and Communications Employees (“Service- och Kommunikationsfacket”; SEKO; about 71,000 members; www098), the Swedish Scouts (Scouterna; about 80,000 members; www099), the Stockholm Disability Rights Federation

(“Funktionsrätt Stockholms län”; about 70,000 members; [www100](#)), the Swedish Uniting Church (Equemeniakyrkan; about 65,000 members; [www101](#)), the Swedish Gaming Association (Sverok; about 55,000 members; [www102](#)), the Animal Rights Association of Sweden (“Djurens Rätt”; about 50,000 members; [www103](#)), the Swedish section of the “International Organisation of Good Templars” (IOGT-NTO; about 46,000 members; [www104](#)), the Stockholm County section of the Swedish Social Democratic Party (“Socialdemokraterna i Stockholm”; about 25,000 members; [www105](#); [www106](#)), the Swedish Association for Culture and Communication (“dokumentation, information och kultur”; DIK; about 21,000 members; [www107](#)), the Swedish Adult Education Association (“Studieförbundet Vuxenskolan”; about 19,000 members; [www108](#)), the Swedish Sports Club (“Allmänna Idrottsklubben”; AIK; about 18,000 members; [www109](#)), the Church of Sweden Youth (“Svenska Kyrkans Unga”; about 13,000 members; [www110](#)), the Norden Association of Sweden (“Föreningen Norden”; about 13,000 members; [www111](#)), the Swedish Association of Young Physicians (“Sveriges Yngre Läkares Förbund”; SYLF; about 12,000 members; [www112](#)), the Green Party of Sweden (“Miljöpartiet de Gröna”; about 10,000 members; [www105](#)), the Swedish Youth Sobriety Association (“Ungdomens Nykterhetsförbunds”; UNF; about 7,000 members; [www113](#)), the “Swedish Federation for Lesbian, Gay, Bisexual, Transgender and Queer Rights” (“Riksförbundet för homosexuellas, bisexuellas, transpersoners och queeras rättigheter”; RFSL; about 7,000 members; [www114](#)), the Swedish Library Association (“Svensk Biblioteksförning”; about 3,000 members; [www115](#)), the Swedish Climate Trade Association (“Föreningen Klimatriksdagen”; [www116](#)), the Swedish Association for Sexuality Education (“Riksförbundet för sexuell upplysning”; RFSU; [www117](#)), 4H Sweden ([www118](#)), and the Skåne section of the Swedish Centre Party (“Centerpartiet i Skåne”; [www119](#)) through their use of the VoteIT decision tool. It is also used by the “Association for Computing Machinery” (ACM; about 110,000 members), by the “Institute of Electrical and Electronics Engineers” (IEEE; about 460,000 members), by the “Internet Society” (ISOC; about 70,000 members), and by USENIX to manage their conference review processes (Mao, 2018; Wenisch, 2018). The IEEE also uses the Schulze method to elect its conference chairs ([www120](#)). It is also used by many housing cooperatives, like “Kingman Hall” (Poundstone, 2008, page 224; [www121](#)), “Technology House” ([www122](#)), “Hillegass-Parker House” ([www123](#)), and “3HäuserProjekt” ([www124](#)). It is used by the Russian ([www125](#)) and the Persian ([www126](#)) Wikipedia sections for the elections of their Arbitration Committees. It is used by the English (Poundstone, 2008, pages 221–222; [www127](#)), the German ([www128](#)), the French, and the Hebrew Wikipedia sections for their internal decision-making processes. It is used by the Pirate Parties of Brazil, Mexico (“wikiPartido Pirata Mexicano”), and Switzerland, by “Slow Food Germany” (about 14,000 members), and by the Synaxon company (about 300 employees; Potschka, 2013; [www129](#)) through their use of the LiquidFeedback decision tool. It is used by the Pirate Party of France through their use of the Congressus decision tool ([www130](#)). It is used by the cities of Turin (about 900,000 inhabitants) and San Donà di Piave (about 40,000 inhabitants) and by the London Borough of Southwark (about 300,000 inhabitants) through their use of the WeGovNow platform, which in turn uses LiquidFeedback ([www131](#)). It is used in Paris (about 2,200,000 inhabitants), Athens (about 660,000 inhabitants), and (again) Turin through the CO3 project, which in turn (again) uses LiquidFeedback ([www132](#)). It is used by the city of Desio (about 42,000 inhabitants) in Italy for participatory budgeting (Comparetto, 2022; [www133](#)). Hardt (2015) writes that the proposed method is used among the Google staff (about

85,000 employees) for internal decisions. Chandler (2008) and B.M. Hill (2008) even write that MTV uses this method to decide which music videos go into rotation.

Furthermore, the proposed method is used by many Internet decision support systems, like the “Debian Vote Engine” (devotee), “Condorcet Internet Voting Service” (CIVS), “Modern Ballots”, GoogleVotes (Hardt, 2015; Paulin, 2019), “L’Expérience Démocratique” (www134), LiquidFeedback (Behrens, 2014a), Selectricity (B.M. Hill, 2008), Votator, schulzevote@DokuWiki (www135), ForceRank, Zeus, CondorcetVote, JungleVote, LunchVote, VoteIT, Airesis, Agreeder, Belenios, Ordinos, Elekto, preftools, HotCRP, Open Assembly, OpenAgora, and OpenSTV/OpaVote.

There has been some debate about an appropriate name for this method. Some people suggested names like “beatpath(s)”, “beatpath method”, “beatpath winner”, “beatpath matrix”, “beatpath tournament”, “path method”, “path voting”, “path winner”, “path matrix”, “widest path method”, “Schwartz sequential dropping” (SSD), and “cloneproof Schwartz sequential dropping” (CSSD). Brearley (1999) suggested names like “descending minimum gross score” (DminGS), “descending minimum augmented gross score” (DminAGS), and “descending minimum doubly augmented gross score” (DminDAGS), depending on how the strength of a pairwise link is measured. Heitzig (2002) suggested names like “strong immunity from binary arguments” (sIm₄) and “sequential dropping towards a spanning tree” (SDST). However, I prefer the name “Schulze method”, not because of academic arrogance, but because the other names do not refer to the method itself but to specific heuristics for implementing it, and so may mislead readers into believing that no other method for implementing it is possible. The calculation of the result of the Schulze method is called “all-pairs maximum capacity paths problem”, “all-pairs bottleneck paths problem” (Sornat, 2021) or “all-pairs directed widest paths problem” (Eppstein, 2021).

In section 2 of this paper, the Schulze method is defined. In section 3, this method is applied to concrete examples. In section 4, this method is analyzed. Detailed descriptions of this method can also be found in publications by Schulze (2003, 2011a, 2016a, 2016b), Tideman (2006, pages 228–232; 2019), Stahl (2006, 2017), McCaffrey (2008a, 2008b), Börgers (2009, pages 37–42), Camps (2008, 2012a, 2012b, 2013, 2014a, 2014b, 2015), Behrens (2014a), D. Müller (2014, 2015, 2019, 2022), and Okumura (2023).

Short descriptions and discussions of the Schulze method can also be found in papers by Green-Armytage (2004), P.A. Taylor (2004), Meskanen (2006a, 2006b, 2008), Wilke (2007), Yue (2007), Grabmeier (2009), Wright (2009), Jennings (2010), Rivest (2010), Švec (2011), Abisheva (2012), Bucovetsky (2012), Gaspers (2012), Grünheid (2012, 2014, 2015, 2016), Negriu (2012), Parkes (2012), Peyre (2012), A. Taylor (2012), Basilio (2013), Lawrence (2013), Menton (2013a, 2013b), J. Müller (2013, 2020), Parkes (2013), Felsenthal (2014), Li (2014), Mattei (2014), Reisch (2014), Gracia-Saz (2015), Schend (2015), V.A. Tushavin (2015, 2016, 2018, 2020), Ádám (2016), Baumeister (2016), Caragiannis (2016), Contucci (2016, 2019), Darlington (2016, 2018, 2023; see also: Schulze, 2024a), Diethelm (2016), Fischer (2016), Hemaspaandra (2016), Pan (2016), Ruiz-Padillo (2016, 2018), Shah (2016), Sosnick (2016), Becirovic (2017), Golyshkov

(2017), Hazra (2017), Hoang (2017), Izetta (2017), D.M. Khudoley (2017, 2021), Kostenko (2017), Louridas (2017), Mathur (2017), Ohm (2017), Pérez-Fernández (2017a, 2017b, 2019), Salamon (2017), Sekar (2017), Skowron (2017), Tozer (2017), Bray (2018), Bubboloni (2018), Fernandez (2018), Hausberger (2018), Mayer (2018), Milosz (2018), Savvateev (2018), Tran (2018), Trapanese (2018), Wilkinson (2018), Abramov (2019), Alekseev (2019), Belayadi (2019, 2021), Budd (2019), Chechliński (2019), Devlin (2019), Krenn (2019), Kurz (2019), McInnes (2019), Aziz (2020), Cellier (2020), Costa (2020), Cummings (2020), Etesamipour (2020), Heilmaier (2020), Mori (2020), Serafini (2020), Sychev (2020), Yaremenko (2020, 2025), Agon (2021), Cachel (2021, 2022), Charignon (2021), Holliday (2021a–2021c, 2023a, 2023b, 2025), Moreno Calderón (2021), Parzen (2021), Podverbnyy (2021), Xia (2021a–2021c, 2022, 2023), Zovko (2021), Frolova (2022), Goaoc (2022), Jelić (2022), Paszkowska (2022), Pintar (2022), Yujie Wang (2022), Aazami (2023), Gori (2023, 2025), Kang (2023), Lanctot (2023), Siahaan (2023), Y.V. Tushavin (2023), Cindio (2024), Matone (2024), Ngoie (2024), Skowron (2024), Bochkov (2025), and Vansprengel (2025).

Applications of the Schulze method are described in papers by Narizzano (2006a–2006d, 2007), Gherzi (2007), Callison-Burch (2009), Lommatzsch (2009), Souza (2009), Prati (2010, 2012), Arguello (2011a–2011c, 2013, 2017), Audhkhasi (2011, 2013), Gelder (2011), Maheswari (2012, 2013), Muldoon (2012), Oryńczak (2012, 2014), Bohne (2013, 2015), Zhou (2013, 2014), Akbib (2014a, 2014b), Garg (2014), Lawonn (2014), S. Wang (2014), Baer (2015a, 2015b), Bountris (2015a, 2015b, 2017), Degeest (2015, 2021), Nguyen (2015), Plösch (2015), Proag (2015), Sompolinsky (2015), Zohar (2015), Aswatha (2016), Barradas-Bautista (2016, 2017), Cai (2016), Chen (2016), Mangeli (2016), Vargas (2016), Verdiesen (2016, 2018), Xexéo (2016), Avramenko (2017), Işıklı (2017, 2023), Moal (2017), Moroney (2018), Bagheri (2019), Laslier (2019), Lotfi (2019), Thomas (2019), Lihu (2020), Melekhov (2020), Mohan (2020), Alves da Silveira (2021), Chambers (2021), Lesaege (2021), Ghajar (2022), Majd (2022), Lambert (2023), Stodt (2023), Corina (2024), Staffieri (2024), and Tosi (2025).

Cases, where the Schulze method is used to evaluate empirical data, are mentioned by Katirai (2006), Morales (2008, 2010), Nanayakkara (2009), Wimmer (2009, 2010), Foale (2010), Gordevičius (2010a, 2010b), Hennecke (2013), Kowalski (2013), Casadebaig (2014), Pallett (2014), Chua (2015), Evita (2015), Rijnsburger (2015, 2017), Bilalov (2016), Dell (2016, 2017), Maio (2016), Vaughan (2016), Erhardt (2017), Gervits (2017), Strasser (2017), Wan (2017), Xue (2017), Darras (2018a–2018d, 2020), Eng (2018), McKenna (2018), Muiños (2018), Al-Rousan (2018), Zarbafian (2018), Zheng (2018, 2020), the BBGLab (2019), Marian (2019, 2020, 2021), McGovern (2019), Sageder (2019), Forster (2020), Fortin (2020), Martínez-Jiménez (2020), Rajeh (2020a–2020d, 2021a, 2021b), Bener (2021), Bureš (2021, 2022), Chang (2021), Fanourakis (2021), Freitas (2021, 2022), Mahmoudpour (2021), Pereira (2021), Safdar (2021), Shen (2021, 2023), Cawood (2022), Reynolds (2022), Santos (2022, 2023), Stanke (2022, 2023, 2024), Zabidov (2022), Zizien (2022), Barbour (2023, 2024), Han (2023), Jing (2023), Sheshko (2023), Sterzik (2023), Yan (2023a, 2023b), Oliver Zendel (2023), Zyl (2023), Campello (2024), Cornish (2024), Culliford (2024), Hosseini (2024), Kinnersley (2024), Maheta (2024), Mills (2024), Tessler (2024), Oleg Zendel (2024), Gao (2025), Revel (2025), Schmalfuss (2025), Skinner (2025), Yun Wang (2025), Zhang (2025), and Cisse (2026).

Implementations of the Schulze method are described in papers by Csar (2018a, 2018b), Holtkamp (2018), Anand (2019), Hertel (2020, 2021), Yadav (2020), Sornat (2021), Cortier (2022), Harrison (2022, 2024a, 2024b), Liedtke (2023), Yang (2023), Anandita (2024), Arora (2024), and Tokar (2025). Aspects of computational social choice, with regard to the Schulze method, are discussed by Gaspers (2012), Parkes (2012), Menton (2013a, 2013b), J. Müller (2013, 2020), Mattei (2014), Reisch (2014), Durand (2015), Schend (2015), Baumeister (2016), Conitzer (2016), Faliszewski (2016), Hemaspaandra (2016), Maushagen (2020, 2021, 2024), Blokhina (2024a, 2024b), and Chen (2025). Metric distortion of the Schulze method is discussed by Goel (2017), Krishnaswamy (2019), Munagala (2019), Pierczyński (2019a, 2019b, 2024), and Kempe (2020). An interesting observation about the Schulze method is that it is Coq-verifiable (Moses, 2017; Pattinson, 2017; Ghale, 2019, 2021; Haines, 2019; Tiwari, 2021a, 2021b, 2022), which is a very strong form of verifiability.

2. Definition of the Schulze Method

2.1. Preliminaries

We presume that A is a finite and non-empty set of alternatives. $C \in \mathbb{N}$ with $1 < C < \infty$ is the number of alternatives in A .

A binary relation $>$ on A is *asymmetric* if it has the following property:

$\forall a, b \in A$, exactly one of the following three statements is valid:

1. $a > b$.
2. $b > a$.
3. $a \approx b$ (where “ $a \approx b$ ” means “neither $a > b$ nor $b > a$ ”).

A binary relation $>$ on A is *irreflexive* if it has the following property:

$$\forall a \in A: a \not> a.$$

A binary relation $>$ on A is *transitive* if it has the following property:

$$\forall a, b, c \in A: ((a > b \text{ and } b > c) \Rightarrow a > c).$$

A binary relation $>$ on A is *negatively transitive* if it has the following property (where “ $a \approx b$ ” means “not $b > a$ ”):

$$\forall a, b, c \in A: ((a \approx b \text{ and } b \approx c) \Rightarrow a \approx c).$$

A binary relation $>$ on A is *linear* (or *total* or *complete*) if it has the following property:

$$\forall a, b \in A: (b \in A \setminus \{a\} \Rightarrow (a > b \text{ or } b > a)).$$

A *strict partial order* is an asymmetric, irreflexive, and transitive relation. A *strict weak order* is a strict partial order that is also negatively transitive. A *linear order* (or *total order* or *complete order*) is a strict weak order that is also linear. A *profile* is a finite and non-empty list of strict weak orders each on A .

Input of the proposed method is a profile V . $N \in \mathbb{N}$ with $0 < N < \infty$ is the number of strict weak orders in $V := \{>_1, \dots, >_N\}$. These strict weak orders will sometimes be called “voters” or “ballots”.

Suppose $V_1 := \{>_1, \dots, >_{N_1}\}$ and $V_2 := \{>_{1'}, \dots, >_{N_2'}\}$ are two profiles each on the same set of alternatives A . Then the concatenation of these two profiles will be denoted $V_1 + V_2 := \{>_1, \dots, >_{N_1}, >_{1'}, \dots, >_{N_2'}\}$.

“ $a >_v b$ ” means “voter $v \in V$ strictly prefers alternative $a \in A$ to alternative b ”. “ $a \approx_v b$ ” means “voter $v \in V$ is indifferent between alternative a and alternative b ”. “ $a \gtrsim_v b$ ” means “ $a >_v b$ or $a \approx_v b$ ”.

Output of the proposed method is (1) a strict partial order O on A and (2) a set $\emptyset \neq S \subseteq A$ of potential winners.

A possible implementation of the Schulze method looks as follows:

Each voter gets a complete list of all alternatives and ranks these alternatives in order of preference. The individual voter may give the same preference to more than one alternative and he may keep alternatives unranked. When a given voter does not rank all alternatives, then this means (1) that this voter strictly prefers all ranked alternatives to all not ranked alternatives and (2) that this voter is indifferent between all not ranked alternatives. The individual voter may also skip preferences; however, skipping preferences has no impact on the result of the elections since only the cast order of the preferences matters, not the absolute numbers.

Suppose $N[e, f] := \|\{v \in V \mid e >_v f\}\|$ is the number of voters who strictly prefer alternative e to alternative f . We presume that the strength of the link ef depends only on $N[e, f]$ and $N[f, e]$. Therefore, the strength of the link ef can be denoted $(N[e, f], N[f, e])$. We presume that a binary relation $>_D$ on $\mathbb{N}_0 \times \mathbb{N}_0$ is defined such that the link ef is stronger than the link gh if and only if $(N[e, f], N[f, e]) >_D (N[g, h], N[h, g])$. $N[e, f]$ is the *support* for the link ef ; $N[f, e]$ is its *opposition*.

Example 1 (*margin*):

When the strength of the link ef is measured by *margin*, then its strength is the difference $N[e, f] - N[f, e]$ between its support $N[e, f]$ and its opposition $N[f, e]$.

$(N[e, f], N[f, e]) >_{\text{margin}} (N[g, h], N[h, g])$ if and only if $N[e, f] - N[f, e] > N[g, h] - N[h, g]$.

Example 2 (*ratio*):

When the strength of the link ef is measured by *ratio*, then its strength is the ratio $N[e,f] / N[f,e]$ between its support $N[e,f]$ and its opposition $N[f,e]$.

$(N[e,f], N[f,e]) >_{ratio} (N[g,h], N[h,g])$ if and only if at least one of the following conditions is satisfied:

1. $N[e,f] > N[f,e]$ and $N[g,h] \leq N[h,g]$.
2. $N[e,f] \geq N[f,e]$ and $N[g,h] < N[h,g]$.
3. $N[e,f] \cdot N[h,g] > N[f,e] \cdot N[g,h]$.
4. $N[e,f] > N[g,h]$ and $N[f,e] \leq N[h,g]$.
5. $N[e,f] \geq N[g,h]$ and $N[f,e] < N[h,g]$.

Comment: Condition 4 in the definition for $>_{ratio}$ is needed e.g. to say that $(N[e,f], N[f,e]) = (5,0)$ is stronger than $(N[g,h], N[h,g]) = (3,0)$; this doesn't follow from conditions 1, 2, 3, and 5. Condition 5 in the definition for $>_{ratio}$ is needed e.g. to say that $(N[e,f], N[f,e]) = (0,3)$ is stronger than $(N[g,h], N[h,g]) = (0,5)$; this doesn't follow from conditions 1 – 4.

Example 3 (*winning votes*):

When the strength of the link ef is measured by *winning votes*, then its strength is measured primarily by its support $N[e,f]$.

$(N[e,f], N[f,e]) >_{win} (N[g,h], N[h,g])$ if and only if at least one of the following conditions is satisfied:

1. $N[e,f] > N[f,e]$ and $N[g,h] \leq N[h,g]$.
2. $N[e,f] \geq N[f,e]$ and $N[g,h] < N[h,g]$.
3. $N[e,f] > N[f,e]$ and $N[g,h] > N[h,g]$ and $N[e,f] > N[g,h]$.
4. $N[e,f] > N[f,e]$ and $N[g,h] > N[h,g]$ and $N[e,f] = N[g,h]$
and $N[f,e] < N[h,g]$.
5. $N[e,f] < N[f,e]$ and $N[g,h] < N[h,g]$ and $N[f,e] < N[h,g]$.
6. $N[e,f] < N[f,e]$ and $N[g,h] < N[h,g]$ and $N[f,e] = N[h,g]$
and $N[e,f] > N[g,h]$.

Example 4 (*losing votes*):

When the strength of the link ef is measured by *losing votes*, then its strength is measured primarily by its opposition $N[f,e]$.

$(N[e,f], N[f,e]) >_{los} (N[g,h], N[h,g])$ if and only if at least one of the following conditions is satisfied:

1. $N[e,f] > N[f,e]$ and $N[g,h] \leq N[h,g]$.
2. $N[e,f] \geq N[f,e]$ and $N[g,h] < N[h,g]$.
3. $N[e,f] > N[f,e]$ and $N[g,h] > N[h,g]$ and $N[f,e] < N[h,g]$.
4. $N[e,f] > N[f,e]$ and $N[g,h] > N[h,g]$ and $N[f,e] = N[h,g]$
and $N[e,f] > N[g,h]$.
5. $N[e,f] < N[f,e]$ and $N[g,h] < N[h,g]$ and $N[e,f] > N[g,h]$.
6. $N[e,f] < N[f,e]$ and $N[g,h] < N[h,g]$ and $N[e,f] = N[g,h]$
and $N[f,e] < N[h,g]$.

The most intuitive definitions for the strength of a link are its *margin* and its *ratio*. However, we only presume that $\succ_D$ is a strict weak order on $\mathbb{N}_0 \times \mathbb{N}_0$.

For some proofs, we have to make additional presumptions for $\succ_D$. We will state explicitly when and where we take use of additional presumptions. Typical additional presumptions for $\succ_D$ are:

(2.1.1) (*positive responsiveness*)

$$\begin{aligned} &\forall (x_1, x_2), (y_1, y_2) \in \mathbb{N}_0 \times \mathbb{N}_0: \\ &((x_1 > y_1 \wedge x_2 \leq y_2) \vee (x_1 \geq y_1 \wedge x_2 < y_2)) \Rightarrow (x_1, x_2) \succ_D (y_1, y_2). \end{aligned}$$

(2.1.2) (*reversal symmetry*)

$$\begin{aligned} &\forall (x_1, x_2), (y_1, y_2) \in \mathbb{N}_0 \times \mathbb{N}_0: \\ &(x_1, x_2) \succ_D (y_1, y_2) \Rightarrow (y_2, y_1) \succ_D (x_2, x_1). \end{aligned}$$

(2.1.3) (*homogeneity*)

$$\begin{aligned} &\forall (x_1, x_2), (y_1, y_2) \in \mathbb{N}_0 \times \mathbb{N}_0 \forall c_1, c_2 \in \mathbb{N}: \\ &(c_1 \cdot x_1, c_1 \cdot x_2) \succ_D (c_1 \cdot y_1, c_1 \cdot y_2) \Rightarrow (c_2 \cdot x_1, c_2 \cdot x_2) \succ_D (c_2 \cdot y_1, c_2 \cdot y_2). \end{aligned}$$

The presumption, that the strength of the link ef depends only on $N[e, f]$ and $N[f, e]$, guarantees (1) that the proposed method satisfies anonymity and neutrality, (2) that adding a ballot, on which all alternatives are ranked equally, cannot change the result of the elections, and (3) that the proposed method is a C2 *Condorcet social choice function* (CSCF) according to Fishburn’s (1977) terminology.

Presumption (2.1.1) says that, when the support of a link increases and its opposition doesn’t increase or when its opposition decreases and its support doesn’t decrease, then the strength of this link increases. So presumption (2.1.1) says that the strength of a link responds to a change of its support or its opposition in the correct manner. Presumption (2.1.1) guarantees that the proposed method satisfies decisiveness (section 4.2), resolvability (section 4.3), Pareto (section 4.4), and monotonicity (section 4.6). When each voter $v \in V$ casts a linear order $\succ_v$ on A , then all definitions for $\succ_D$, that satisfy presumption (2.1.1), are identical.

Presumption (2.1.2) says that, the stronger the link (x_1, x_2) gets, the weaker the opposite link (x_2, x_1) gets. Presumption (2.1.2) basically says that, when the individual ballots $\succ_v$ are reversed for all voters $v \in V$, then also the order of the links $(x_1, x_2) \succ_D (y_1, y_2)$ is reversed.

Homogeneity means that the result depends only on the proportion of ballots of each type, not on their absolute numbers. Presumption (2.1.3) guarantees that the proposed method satisfies homogeneity.

Presumptions (2.1.1) and (2.1.2) together guarantee that presumption (2.1.5) is satisfied. Presumption (2.1.5) guarantees that the proposed method satisfies majority criteria.

$\succ_{\text{margin}}$, $\succ_{\text{ratio}}$, $\succ_{\text{win}}$, and $\succ_{\text{los}}$ each satisfy (2.1.1) – (2.1.3).

Definitions:

Suppose $(x_1, x_2) \in \mathbb{N}_0 \times \mathbb{N}_0$.

If $x_1 > x_2$, then (x_1, x_2) is a *victory*.

If $x_1 = x_2$, then (x_1, x_2) is a *tie*.

If $x_1 < x_2$, then (x_1, x_2) is a *defeat*.

Corollary (2.1.4):

If $>_D$ satisfies presumption (2.1.2), then all ties have equivalent strengths. In short:

(2.1.4) (*equivalence of ties*)

$$\forall x, y \in \mathbb{N}_0: (x, x) \approx_D (y, y).$$

Proof of corollary (2.1.4):

Suppose $(x, x) >_D (y, y)$ for some $x, y \in \mathbb{N}_0$. Then with (2.1.2), we get $(y, y) >_D (x, x)$. But this is a contradiction to the presumption $(x, x) >_D (y, y)$ and to the presumption that $>_D$ is a strict weak order. $\square$

Corollary (2.1.5):

If $>_D$ satisfies presumptions (2.1.1) and (2.1.2), then (i) every victory is stronger than every tie and (ii) every tie is stronger than every pairwise defeat. In short:

(2.1.5) (*majority*)

$$\begin{aligned} &\forall (x_1, x_2), (y_1, y_2) \in \mathbb{N}_0 \times \mathbb{N}_0: \\ &((x_1 > x_2 \wedge y_1 \leq y_2) \vee (x_1 \geq x_2 \wedge y_1 < y_2)) \Rightarrow (x_1, x_2) >_D (y_1, y_2). \end{aligned}$$

Proof of corollary (2.1.5):

Suppose $(x_1, x_2) \in \mathbb{N}_0 \times \mathbb{N}_0$ with $x_1 > x_2$ is a victory.

Suppose $(y_1, y_2) \in \mathbb{N}_0 \times \mathbb{N}_0$ with $y_1 = y_2$ is a tie.

Suppose $(z_1, z_2) \in \mathbb{N}_0 \times \mathbb{N}_0$ with $z_1 < z_2$ is a defeat.

With (2.1.1), we get: $(x_1, x_2) >_D (x_2, x_2)$.

With (2.1.4), we get: $(x_2, x_2) \approx_D (y_1, y_2)$.

With (2.1.4), we get: $(y_1, y_2) \approx_D (z_1, z_1)$.

With (2.1.1), we get: $(z_1, z_1) >_D (z_1, z_2)$.

Therefore, we get: $(x_1, x_2) >_D (x_2, x_2) \approx_D (y_1, y_2) \approx_D (z_1, z_1) >_D (z_1, z_2)$.

Thus, we get (2.1.5). $\square$

Suppose $\emptyset \neq \mathcal{M} \subset \mathbb{N}_0 \times \mathbb{N}_0$ is finite and non-empty. Then " $\max_D \mathcal{M}$ ", the set of maximum elements of $\mathcal{M}$, and " $\min_D \mathcal{M}$ ", the set of minimum elements of $\mathcal{M}$, are defined as follows: $(\beta_1, \beta_2) \in \max_D \mathcal{M}$ if and only if (1) $(\beta_1, \beta_2) \in \mathcal{M}$ and (2) $(\beta_1, \beta_2) \succeq_D (\delta_1, \delta_2) \forall (\delta_1, \delta_2) \in \mathcal{M}$. $(\gamma_1, \gamma_2) \in \min_D \mathcal{M}$ if and only if (1) $(\gamma_1, \gamma_2) \in \mathcal{M}$ and (2) $(\gamma_1, \gamma_2) \preceq_D (\delta_1, \delta_2) \forall (\delta_1, \delta_2) \in \mathcal{M}$.

We write " $(\beta_1, \beta_2) := \max_D \mathcal{M}$ " and " $(\gamma_1, \gamma_2) := \min_D \mathcal{M}$ " for " (β_1, β_2) is an arbitrarily chosen element of $\max_D \mathcal{M}$ " and " (γ_1, γ_2) is an arbitrarily chosen element of $\min_D \mathcal{M}$ ".

2.2. Basic Definitions

In this section, the Schulze method is defined. Concrete examples can be found in section 3.

Basic idea of the Schulze method is that the *strength* of the indirect comparison "alternative a vs. alternative b " is the *strength* of the *strongest path* $a \equiv c(1), \dots, c(n) \equiv b$ from alternative $a \in A$ to alternative $b \in A \setminus \{a\}$ and that the *strength* of a path is the *strength* $(N[c(i), c(i+1)], N[c(i+1), c(i)])$ of its *weakest link* $c(i), c(i+1)$.

The Schulze method is defined as follows:

A *path* from alternative $x \in A$ to alternative $y \in A \setminus \{x\}$ is a sequence of alternatives $c(1), \dots, c(n) \in A$ with the following properties:

1. $x \equiv c(1)$.
2. $y \equiv c(n)$.
3. $n \in \mathbb{N}$ with $2 \leq n \leq C$.
4. For all $i, j \in \{1, \dots, n\}$: $i \neq j \Rightarrow c(i) \in A \setminus \{c(j)\}$.

The *strength* of the path $c(1), \dots, c(n)$ is

$$\min_D \{ (N[c(i), c(i+1)], N[c(i+1), c(i)]) \mid i = 1, \dots, (n-1) \}.$$

In other words: The strength of a path is the strength of its weakest link.

When a path $c(1), \dots, c(n)$ has the strength $(z_1, z_2) \in \mathbb{N}_0 \times \mathbb{N}_0$, then the *critical links* of this path are the links with $(N[c(i), c(i+1)], N[c(i+1), c(i)]) \approx_D (z_1, z_2)$.

$$P_D[a, b] := \max_D \{ \min_D \{ (N[c(i), c(i+1)], N[c(i+1), c(i)]) \mid i = 1, \dots, (n-1) \} \mid c(1), \dots, c(n) \text{ is a path from alternative } a \text{ to alternative } b \}.$$

In other words: $P_D[a, b] \in \mathbb{N}_0 \times \mathbb{N}_0$ is the strength of the strongest path from alternative $a \in A$ to alternative $b \in A \setminus \{a\}$.

(2.2.1) The binary relation $\mathcal{O}$ on A is defined as follows:

$$ab \in \mathcal{O} : \Leftrightarrow P_D[a, b] \succ_D P_D[b, a].$$

(2.2.2) $\mathcal{S} := \{ a \in A \mid \forall b \in A \setminus \{a\}: ba \notin \mathcal{O} \}$ is the set of *potential winners*.

When there is only one potential winner $S = \{a\}$, then this alternative is a *unique winner*.

When $P_D[a,b] >_D P_D[b,a]$, then we say “alternative a disqualifies alternative b ” or “alternative a dominates alternative b ”.

As the link ab is already a path from alternative a to alternative b of strength $(N[a,b], N[b,a])$, we get

$$(2.2.3) \quad \forall a, b \in A: P_D[a,b] \approx_D (N[a,b], N[b,a]).$$

With (2.2.1) and (2.2.3), we get

$$(2.2.4) \quad (N[a,b], N[b,a]) >_D P_D[b,a] \Rightarrow ab \in O.$$

A *route* from alternative $x \in A$ to alternative $y \in A \setminus \{x\}$ is a sequence of alternatives $c(1), \dots, c(n) \in A$ with the following properties:

1. $x \equiv c(1)$.
2. $y \equiv c(n)$.
3. $n \in \mathbb{N}$ with $2 \leq n < \infty$.
4. For all $i = 1, \dots, (n-1)$: $c(i+1) \in A \setminus \{c(i)\}$.

We have

$$(2.2.5) \quad \forall a, b, c \in A: \min_D \{ P_D[a,b], P_D[b,c] \} \approx_D P_D[a,c].$$

Otherwise, if $\min_D \{ P_D[a,b], P_D[b,c] \}$ was strictly larger than $P_D[a,c]$, then this would be a contradiction to the definition of $P_D[a,c]$ since there would be a route from alternative a to alternative c via alternative b with a strength of more than $P_D[a,c]$; and if this route was not itself a path (because it passed through some alternatives more than once) then some subset of its links would form a path from alternative a to alternative c with a strength of more than $P_D[a,c]$.

The asymmetry of O follows directly from the asymmetry of $>_D$. The irreflexivity of O follows directly from the irreflexivity of $>_D$. Furthermore, in section 4.1, we will see that the binary relation O is transitive. This guarantees that there is always at least one potential winner.

Suppose $\mathcal{LO}_A$ is the set of linear orders on A . Suppose O_0 is the binary relation defined in (2.2.1). Then we define *potential winning rankings* as follows:

$$(2.2.6) \quad O_1 \in \mathcal{LO}_A \text{ is a } \textit{potential winning ranking} \text{ of the Schulze method: } \Leftrightarrow O_0 \subseteq O_1.$$

In section 4.1, we will prove that the binary relation O_0 , as defined in (2.2.1), is a strict partial order. Therefore, it is guaranteed that there is always at least one potential winning ranking.

2.3. Implementation

2.3.1. Part 1

In section 2.3.1, we explain how to calculate (1) the strict partial order O on A and (2) the set $\emptyset \neq S \subseteq A$ of potential winners, as defined in section 2.2.

The strength $P_D[i,j]$ of the strongest path from alternative $i \in A$ to alternative $j \in A \setminus \{i\}$ can be calculated with the Floyd-Warshall (Floyd, 1962; Warshall, 1962) algorithm. The runtime to calculate the strengths of all strongest paths is $O(C^3)$, where C is the number of alternatives in A .

Input: $N[i,j] \in \mathbb{N}_0$ is the number of voters who strictly prefer alternative $i \in A$ to alternative $j \in A \setminus \{i\}$.

Output: $P_D[i,j] \in \mathbb{N}_0 \times \mathbb{N}_0$ is the strength of the strongest path from alternative $i \in A$ to alternative $j \in A \setminus \{i\}$.

$pred[i,j] \in A \setminus \{j\}$ is the predecessor of alternative j in the strongest path from alternative $i \in A$ to alternative $j \in A \setminus \{i\}$.

O is the binary relation as defined in (2.2.1).

“winner[i] = true” if and only if $i \in S$.

Stage 1 (initialization):

```

1  for  $i := 1$  to  $C$ 
2  begin
3      for  $j := 1$  to  $C$ 
4      begin
5          if ( $i \neq j$ ) then
6              begin
7                   $P_D[i,j] := (N[i,j], N[j,i])$ 
8                   $pred[i,j] := i$ 
9              end
10         end
11     end
```

Stage 2 (calculation of the strengths of the strongest paths):

```

12  for  $i := 1$  to  $C$ 
13  begin
14    for  $j := 1$  to  $C$ 
15    begin
16      if ( $i \neq j$ ) then
17        begin
18          for  $k := 1$  to  $C$ 
19          begin
20            if ( $i \neq k$ ) then
21              begin
22                if ( $j \neq k$ ) then
23                  begin
24                    if ( $P_D[j,k] <_D \min_D \{ P_D[j,i], P_D[i,k] \}$ ) then
25                      begin
26                         $P_D[j,k] := \min_D \{ P_D[j,i], P_D[i,k] \}$ 
27                         $pred[j,k] := pred[i,k]$ 
28                      end
29                    end
30                  end
31                end
32              end
33            end
34          end

```

Stage 3 (calculation of the binary relation O and the set of potential winners):

```

35  for  $i := 1$  to  $C$ 
36  begin
37     $winner[i] := true$ 
38    for  $j := 1$  to  $C$ 
39    begin
40      if ( $i \neq j$ ) then
41        begin
42          if ( $P_D[j,i] >_D P_D[i,j]$ ) then
43            begin
44               $ji \in O$ 
45               $winner[i] := false$ 
46            end
47          else
48            begin
49               $ji \notin O$ 
50            end
51          end
52        end
53      end

```

(α) It cannot be stressed frequently enough that the order of the indices in the triple-loop of the Floyd-Warshall algorithm is not irrelevant. When i is the index of the outer loop of the triple-loop of the Floyd-Warshall algorithm, then the clause (line 24) must be “ if ($P_D[j,k] <_D \min_D \{ P_D[j,i], P_D[i,k] \} \)) ”. Otherwise, it is not guaranteed that a single pass through the triple-loop of the Floyd-Warshall algorithm is sufficient to find the strongest paths.$

(β) With the predecessor matrix $pred[i,j]$, we can recursively determine the strongest paths. Suppose we want to determine the strongest path $c(1), \dots, c(n)$ from alternative $a \in A$ to alternative $b \in A \setminus \{a\}$. Then we start with

$$n := 1$$

$$d(1) := b$$

We repeat

$$n := n + 1$$

$$d(n) := pred[a, d(n-1)]$$

until we get $d(n) = a$ for some $n \in \mathbb{N}$. The strongest path $c(1), \dots, c(n)$ from alternative a to alternative b is then given by $d(n), \dots, d(1)$.

(γ) The runtime to calculate the pairwise matrix is $O(N \cdot (C^2))$. The runtime of the Floyd-Warshall algorithm, as defined in this section, is $O(C^3)$. Therefore, the total runtime to calculate the binary relation $\mathcal{O}$, as defined in (2.2.1), and the set $\mathcal{S}$, as defined in (2.2.2), is $O(N \cdot (C^2) + C^3)$.

2.3.2. Part 2

In section 2.3.2, we explain how to check whether a concrete alternative $m \in A$ is a potential winner.

Sometimes, we don’t want to calculate all potential winners. We only want to check for a concrete alternative m whether it is a potential winner. In this case, we don’t have to calculate the strengths $P_D[i,j]$ of the strongest paths from every alternative $i \in A$ to every other alternative $j \in A \setminus \{i\}$. It is sufficient to calculate the strengths of the strongest paths from alternative m to every other alternative $i \in A \setminus \{m\}$ and the strengths of the strongest paths from every other alternative $i \in A \setminus \{m\}$ to alternative m . This can be done with the Dijkstra (1959) algorithm in a runtime $O(C^2)$.

Input: $N[i,j] \in \mathbb{N}_0$ is the number of voters who strictly prefer alternative $i \in A$ to alternative $j \in A \setminus \{i\}$.

$m \in A$ is that alternative for which we want to check whether it is a potential winner.

Output: $P_D[m,i] \in \mathbb{N}_0 \times \mathbb{N}_0$ is the strength of the strongest path from alternative m to alternative $i \in A \setminus \{m\}$.

$P_D[i,m] \in \mathbb{N}_0 \times \mathbb{N}_0$ is the strength of the strongest path from alternative $i \in A \setminus \{m\}$ to alternative m .

“winner = true” if and only if m is a potential winner.

Stage 1 (initialization):

```

1  |  $n := 1$ 
2  | if (  $m = 1$  ) then
3  |   begin
4  |      $n := 2$ 
5  |   end

```

Stage 2 (calculation of the strengths of the strongest paths from alternative m to every other alternative $i \in A \setminus \{m\}$):

```

6  | for  $i := 1$  to  $C$ 
7  |   begin
8  |     if (  $i \neq m$  ) then
9  |       begin
10 |          $P_D[m,i] := (N[m,i], N[i,m])$ 
11 |          $marked[i] := false$ 
12 |       end
13 |     end
14 |      $marked[m] := true$ 
15 |     for  $i := 1$  to (  $C - 1$  )
16 |       begin
17 |          $(x_1, x_2) := P_D[m, n]$ 
18 |          $j := n$ 
19 |         for  $k := 1$  to  $C$ 
20 |           begin
21 |             if (  $marked[k] = false$  ) then
22 |               begin
23 |                 if ( (  $(x_1, x_2) <_D P_D[m, k]$  ) or (  $marked[j] = true$  ) ) then
24 |                   begin
25 |                      $(x_1, x_2) := P_D[m, k]$ 
26 |                      $j := k$ 
27 |                   end
28 |                 end
29 |               end
30 |              $marked[j] := true$ 
31 |             for  $k := 1$  to  $C$ 
32 |               begin
33 |                 if (  $marked[k] = false$  ) then
34 |                   begin
35 |                     if (  $P_D[m, k] <_D \min_D \{ P_D[m, j], (N[j, k], N[k, j]) \}$  ) then
36 |                       begin
37 |                          $P_D[m, k] := \min_D \{ P_D[m, j], (N[j, k], N[k, j]) \}$ 
38 |                       end
39 |                     end
40 |                   end
41 |                 end

```

Stage 3 (calculation of the strengths of the strongest paths from every other alternative $i \in A \setminus \{m\}$ to alternative m):

```

42 | for  $i := 1$  to  $C$ 
43 | begin
44 |   if (  $i \neq m$  ) then
45 |     begin
46 |        $P_D[i,m] := (N[i,m], N[m,i])$ 
47 |        $marked[i] := false$ 
48 |     end
49 |   end
50 |    $marked[m] := true$ 
51 |   for  $i := 1$  to (  $C - 1$  )
52 |     begin
53 |        $(x_1, x_2) := P_D[n, m]$ 
54 |        $j := n$ 
55 |       for  $k := 1$  to  $C$ 
56 |         begin
57 |           if (  $marked[k] = false$  ) then
58 |             begin
59 |               if ( (  $(x_1, x_2) <_D P_D[k, m]$  ) or (  $marked[j] = true$  ) ) then
60 |                 begin
61 |                    $(x_1, x_2) := P_D[k, m]$ 
62 |                    $j := k$ 
63 |                 end
64 |               end
65 |             end
66 |            $marked[j] := true$ 
67 |           for  $k := 1$  to  $C$ 
68 |             begin
69 |               if (  $marked[k] = false$  ) then
70 |                 begin
71 |                   if (  $P_D[k, m] <_D \min_D \{ P_D[j, m], (N[k, j], N[j, k]) \}$  ) then
72 |                     begin
73 |                        $P_D[k, m] := \min_D \{ P_D[j, m], (N[k, j], N[j, k]) \}$ 
74 |                     end
75 |                   end
76 |                 end
77 |             end

```

Stage 4 (checking whether alternative m is a potential winner):

```

78 |  $winner := true$ 
79 | for  $i := 1$  to  $C$ 
80 | begin
81 |   if (  $i \neq m$  ) then
82 |     begin
83 |       if (  $P_D[i, m] >_D P_D[m, i]$  ) then
84 |         begin
85 |            $winner := false$ 
86 |         end
87 |       end
88 |     end

```

2.3.3. Part 3

Suppose that we have already guessed or determined that the statement “ $ab \in O$ ” is true. In section 2.3.3, we will show how we can then demonstrate the correctness of this statement.

To demonstrate that the statement “ $ab \in O$ ” is true, we have to present a $(x_1, x_2) \in \mathbb{N}_0 \times \mathbb{N}_0$ such that (1) there is a path from alternative a to alternative b with a strength of at least (x_1, x_2) and (2) there is no path from alternative b to alternative a with a strength of at least (x_1, x_2) .

To demonstrate that there is a path from alternative a to alternative b with a strength of at least (x_1, x_2) , we can simply use the sequence $c(1), \dots, c(n)$ as calculated in remark β of section 2.3.1 or the path as determined in section 2.3.2 or a path found by guesswork. The runtime to verify that a given sequence is really a path from alternative a to alternative b with a strength of at least (x_1, x_2) is $O(C)$.

When there is no path from alternative b to alternative a with a strength of at least (x_1, x_2) , we can demonstrate this by presenting two sets B_1 and B_2 such that

$$(2.3.3.1) \quad b \in B_1.$$

$$(2.3.3.2) \quad a \in B_2.$$

$$(2.3.3.3) \quad B_1 \cup B_2 = A.$$

$$(2.3.3.4) \quad B_1 \cap B_2 = \emptyset.$$

$$(2.3.3.5) \quad \forall i \in B_1 \forall j \in B_2: (N[i, j], N[j, i]) <_D (x_1, x_2).$$

When B_1 and B_2 are given, then the runtime to verify that (2.3.3.1) – (2.3.3.5) are satisfied is $O(C^2)$.

(α) Suppose that we have not calculated the strengths of the strongest paths from every alternative $i \in A$ to every other alternative $j \in A \setminus \{i\}$, but that we have found a path from alternative a to alternative b of strength $(x_1, x_2) \in \mathbb{N}_0 \times \mathbb{N}_0$ and want to check whether this path is sufficient so that alternative a disqualifies alternative b (i.e. $ab \in O$).

Then we can calculate the sets B_1 and B_2 , for example, with the “breadth-first search” (BFS) algorithm as follows. The runtime to calculate the sets B_1 and B_2 is $O(C^2)$.

Input: $N[i, j] \in \mathbb{N}_0$ is the number of voters who strictly prefer alternative $i \in A$ to alternative $j \in A \setminus \{i\}$.

$(x_1, x_2) \in \mathbb{N}_0 \times \mathbb{N}_0$.

$a, b \in A$ are those alternatives for which we want to show that there is no path from alternative b to alternative a with a strength of at least (x_1, x_2) .

Output: the sets B_1 and B_2 as described above

```

1   $B_1 := \{b\}$ 
2   $m := 1$ 
3   $array1[1] := b$ 
4  while (  $m > 0$  ) do
5  begin
6       $n := m$ 
7      for  $k := 1$  to  $m$ 
8      begin
9           $array2[k] := array1[k]$ 
10     end
11      $m := 0$ 
12     for  $i := 1$  to  $n$ 
13     begin
14          $j := array2[i]$ 
15         for  $k := 1$  to  $C$ 
16         begin
17             if (  $k \notin B_1$  ) then
18             begin
19                 if (  $(N[j, k], N[k, j]) \succeq_D (x_1, x_2)$  ) then
20                 begin
21                      $B_1 := B_1 \cup \{k\}$ 
22                      $m := m + 1$ 
23                      $array1[m] := k$ 
24                 end
25             end
26         end
27     end
28 end
29  $B_2 := A \setminus B_1$ 

```

When, at some point, alternative a is added to the set B_1 , then this means that a path from alternative a to alternative b of strength (x_1, x_2) is not sufficient so that alternative a disqualifies alternative b .

(β) Suppose (1) that we have calculated the strengths of the strongest paths from every alternative $i \in A$ to every other alternative $j \in A \setminus \{i\}$, as described in section 2.3.1, and (2) that the statement “ $ab \in O$ ” is true. Then B_1 and B_2 are given as follows:

$$B_1 := (\{b\} \cup \{ c \in A \mid P_D[b,c] \approx_D (x_1, x_2) \}).$$

$$B_2 := A \setminus B_1.$$

2.4. Arborescences and Anti-Arborescences

An *arborescence* $\mathcal{A} \subset A \times A$ is a set of $C-1$ links such that there is a vertex $x \in A$, the so-called *root*, such that, for every other vertex $y \in A \setminus \{x\}$, there is a directed path in $\mathcal{A}$ from vertex x to vertex y .

An *anti-arborescence* $\mathcal{D} \subset A \times A$ is a set of $C-1$ links such that there is a vertex $x \in A$, the so-called *anti-root*, such that, for every other vertex $y \in A \setminus \{x\}$, there is a directed path in $\mathcal{D}$ from vertex y to vertex x .

When the Floyd-Warshall algorithm is used, as defined in section 2.3.1, then the links of the strongest paths from alternative x to every other alternative form an arborescence with alternative x as its root. This fact will be used in sections 4.3, 4.13, 4.14.3, 4.14.4, and 4.14.5. Throughout section 3, this arborescence will be shown in the column “... to every other alternative” in the tables with the strongest paths.

When the Floyd-Warshall algorithm is used, as defined in section 2.3.1, then the links of the strongest paths from every other alternative to alternative x form an anti-arborescence with alternative x as its anti-root. Throughout section 3, this anti-arborescence will be shown in the row “from every other alternative ...” in the tables with the strongest paths.

3. Examples

Throughout section 3, we presume that $\succ_D$ satisfies (2.1.1) so that, when each voter $v \in V$ casts a linear order $\succ_v$ on A , all definitions for $\succ_D$ are identical.

3.1. Example 1

Example 1:

8 voters $a \succ_v c \succ_v d \succ_v b$
2 voters $b \succ_v a \succ_v d \succ_v c$
4 voters $c \succ_v d \succ_v b \succ_v a$
4 voters $d \succ_v b \succ_v a \succ_v c$
3 voters $d \succ_v c \succ_v b \succ_v a$

$N[i,j] \in \mathbb{N}_0$ is the number of voters who strictly prefer alternative $i \in A$ to alternative $j \in A \setminus \{i\}$. In example 1, the pairwise matrix N looks as follows:

	$N[*,a]$	$N[*,b]$	$N[*,c]$	$N[*,d]$
$N[a,*]$	---	8	14	10
$N[b,*]$	13	---	6	2
$N[c,*]$	7	15	---	12
$N[d,*]$	11	19	9	---

The following digraph illustrates the graph theoretic interpretation of pairwise elections. If $N[i,j] > N[j,i]$, then there is a link from vertex i to vertex j of strength $(N[i,j], N[j,i])$:

The above digraph can be used to determine the strengths of the strongest paths. In the following, “ $x, (Z_1, Z_2), y$ ” means “ $(N[x, y], N[y, x]) = (Z_1, Z_2)$ ”.

$a \rightarrow b$: There are 2 paths from alternative a to alternative b .

Path 1: $a, (14, 7), c, (15, 6), b$
with a strength of $\min_D \{ (14, 7), (15, 6) \} \approx_D (14, 7)$.

Path 2: $a, (14, 7), c, (12, 9), d, (19, 2), b$
with a strength of $\min_D \{ (14, 7), (12, 9), (19, 2) \} \approx_D (12, 9)$.

So the strength of the strongest path from alternative a to alternative b is $\max_D \{ (14, 7), (12, 9) \} \approx_D (14, 7)$.

$a \rightarrow c$: There is only one path from alternative a to alternative c .

Path 1: $a, (14, 7), c$
with a strength of $(14, 7)$.

So the strength of the strongest path from alternative a to alternative c is $(14, 7)$.

$a \rightarrow d$: There is only one path from alternative a to alternative d .

Path 1: $a, (14, 7), c, (12, 9), d$
with a strength of $\min_D \{ (14, 7), (12, 9) \} \approx_D (12, 9)$.

So the strength of the strongest path from alternative a to alternative d is $(12, 9)$.

$b \rightarrow a$: There is only one path from alternative b to alternative a .

Path 1: $b, (13, 8), a$
with a strength of $(13, 8)$.

So the strength of the strongest path from alternative b to alternative a is $(13, 8)$.

$b \rightarrow c$: There is only one path from alternative b to alternative c .

Path 1: $b, (13,8), a, (14,7), c$
with a strength of $\min_D \{ (13,8), (14,7) \} \approx_D (13,8)$.

So the strength of the strongest path from alternative b to alternative c is $(13,8)$.

$b \rightarrow d$: There is only one path from alternative b to alternative d .

Path 1: $b, (13,8), a, (14,7), c, (12,9), d$
with a strength of $\min_D \{ (13,8), (14,7), (12,9) \} \approx_D (12,9)$.

So the strength of the strongest path from alternative b to alternative d is $(12,9)$.

$c \rightarrow a$: There are 3 paths from alternative c to alternative a .

Path 1: $c, (15,6), b, (13,8), a$
with a strength of $\min_D \{ (15,6), (13,8) \} \approx_D (13,8)$.

Path 2: $c, (12,9), d, (11,10), a$
with a strength of $\min_D \{ (12,9), (11,10) \} \approx_D (11,10)$.

Path 3: $c, (12,9), d, (19,2), b, (13,8), a$
with a strength of $\min_D \{ (12,9), (19,2), (13,8) \} \approx_D (12,9)$.

So the strength of the strongest path from alternative c to alternative a is $\max_D \{ (13,8), (11,10), (12,9) \} \approx_D (13,8)$.

$c \rightarrow b$: There are 2 paths from alternative c to alternative b .

Path 1: $c, (15,6), b$
with a strength of $(15,6)$.

Path 2: $c, (12,9), d, (19,2), b$
with a strength of $\min_D \{ (12,9), (19,2) \} \approx_D (12,9)$.

So the strength of the strongest path from alternative c to alternative b is $\max_D \{ (15,6), (12,9) \} \approx_D (15,6)$.

$c \rightarrow d$: There is only one path from alternative c to alternative d .

Path 1: $c, (12,9), d$
with a strength of $(12,9)$.

So the strength of the strongest path from alternative c to alternative d is $(12,9)$.

$d \rightarrow a$: There are 2 paths from alternative d to alternative a .

Path 1: $d, (11,10), a$
with a strength of $(11,10)$.

Path 2: $d, (19,2), b, (13,8), a$
with a strength of $\min_D \{ (19,2), (13,8) \} \approx_D (13,8)$.

So the strength of the strongest path from alternative d to alternative a is $\max_D \{ (11,10), (13,8) \} \approx_D (13,8)$.

$d \rightarrow b$: There are 2 paths from alternative d to alternative b .

Path 1: $d, (11,10), a, (14,7), c, (15,6), b$
with a strength of $\min_D \{ (11,10), (14,7), (15,6) \} \approx_D (11,10)$.

Path 2: $d, (19,2), b$
with a strength of $(19,2)$.

So the strength of the strongest path from alternative d to alternative b is $\max_D \{ (11,10), (19,2) \} \approx_D (19,2)$.

$d \rightarrow c$: There are 2 paths from alternative d to alternative c .

Path 1: $d, (11,10), a, (14,7), c$
with a strength of $\min_D \{ (11,10), (14,7) \} \approx_D (11,10)$.

Path 2: $d, (19,2), b, (13,8), a, (14,7), c$
with a strength of $\min_D \{ (19,2), (13,8), (14,7) \} \approx_D (13,8)$.

So the strength of the strongest path from alternative d to alternative c is $\max_D \{ (11,10), (13,8) \} \approx_D (13,8)$.

The following table lists the strongest paths, as determined by the Floyd-Warshall algorithm, as defined in section 2.3.1. The critical links of the strongest paths are underlined:

	... to <i>a</i>	... to <i>b</i>	... to <i>c</i>	... to <i>d</i>	... to every other alternative
from <i>a</i> ...	---	 <i>a</i> , <u>(14,7)</u> , <i>c</i> , (15,6), <i>b</i>	 <i>a</i> , <u>(14,7)</u> , <i>c</i>	 <i>a</i> , (14,7), <i>c</i> , <u>(12,9)</u> , <i>d</i>	
from <i>b</i> ...	 <i>b</i> , <u>(13,8)</u> , <i>a</i>	---	 <i>b</i> , (13,8), <i>a</i> , (14,7), <i>c</i>	 <i>b</i> , (13,8), <i>a</i> , (14,7), <i>c</i> , <u>(12,9)</u> , <i>d</i>	
from <i>c</i> ...	 <i>c</i> , (15,6), <i>b</i> , <u>(13,8)</u> , <i>a</i>	 <i>c</i> , <u>(15,6)</u> , <i>b</i>	---	 <i>c</i> , <u>(12,9)</u> , <i>d</i>	
from <i>d</i> ...	 <i>d</i> , (19,2), <i>b</i> , <u>(13,8)</u> , <i>a</i>	 <i>d</i> , <u>(19,2)</u> , <i>b</i>	 <i>d</i> , (19,2), <i>b</i> , <u>(13,8)</u> , <i>a</i> , (14,7), <i>c</i>	---	
from every other alternative ...					---

The strengths of the strongest paths are:

	$P_D[*,a]$	$P_D[*,b]$	$P_D[*,c]$	$P_D[*,d]$
$P_D[a,*]$	---	(14,7)	(14,7)	(12,9)
$P_D[b,*]$	(13,8)	---	(13,8)	(12,9)
$P_D[c,*]$	(13,8)	(15,6)	---	(12,9)
$P_D[d,*]$	(13,8)	(19,2)	(13,8)	---

$xy \in \mathcal{O}$ if and only if $P_D[x,y] >_D P_D[y,x]$. So in example 1, we get $\mathcal{O} = \{ab, ac, cb, da, db, dc\}$.

$x \in \mathcal{S}$ if and only if $yx \notin \mathcal{O}$ for all $y \in A \setminus \{x\}$. So in example 1, we get $\mathcal{S} = \{d\}$.

Suppose, the strongest paths are calculated with the Floyd-Warshall algorithm, as defined in section 2.3.1. Then the following table documents the $C \cdot (C-1) \cdot (C-2) = 24$ steps of the Floyd-Warshall algorithm.

We start with

- $P_D[i,j] := (N[i,j], N[j,i])$ for all $i \in A$ and $j \in A \setminus \{i\}$.
- $pred[i,j] := i$ for all $i \in A$ and $j \in A \setminus \{i\}$.

	i	j	k	$P_D[j,k]$	$P_D[j,i]$	$P_D[i,k]$	$pred[j,k]$	$pred[i,k]$	result
1	a	b	c	(6,15)	(13,8)	(14,7)	b	a	$P_D[b,c]$ is updated from (6,15) to (13,8); $pred[b,c]$ is updated from b to a .
2	a	b	d	(2,19)	(13,8)	(10,11)	b	a	$P_D[b,d]$ is updated from (2,19) to (10,11); $pred[b,d]$ is updated from b to a .
3	a	c	b	(15,6)	(7,14)	(8,13)	c	a	
4	a	c	d	(12,9)	(7,14)	(10,11)	c	a	
5	a	d	b	(19,2)	(11,10)	(8,13)	d	a	
6	a	d	c	(9,12)	(11,10)	(14,7)	d	a	$P_D[d,c]$ is updated from (9,12) to (11,10); $pred[d,c]$ is updated from d to a .
7	b	a	c	(14,7)	(8,13)	(13,8)	a	a	
8	b	a	d	(10,11)	(8,13)	(10,11)	a	a	
9	b	c	a	(7,14)	(15,6)	(13,8)	c	b	$P_D[c,a]$ is updated from (7,14) to (13,8); $pred[c,a]$ is updated from c to b .
10	b	c	d	(12,9)	(15,6)	(10,11)	c	a	
11	b	d	a	(11,10)	(19,2)	(13,8)	d	b	$P_D[d,a]$ is updated from (11,10) to (13,8); $pred[d,a]$ is updated from d to b .
12	b	d	c	(11,10)	(19,2)	(13,8)	a	a	$P_D[d,c]$ is updated from (11,10) to (13,8).
13	c	a	b	(8,13)	(14,7)	(15,6)	a	c	$P_D[a,b]$ is updated from (8,13) to (14,7); $pred[a,b]$ is updated from a to c .
14	c	a	d	(10,11)	(14,7)	(12,9)	a	c	$P_D[a,d]$ is updated from (10,11) to (12,9); $pred[a,d]$ is updated from a to c .
15	c	b	a	(13,8)	(13,8)	(13,8)	b	b	
16	c	b	d	(10,11)	(13,8)	(12,9)	a	c	$P_D[b,d]$ is updated from (10,11) to (12,9); $pred[b,d]$ is updated from a to c .
17	c	d	a	(13,8)	(13,8)	(13,8)	b	b	
18	c	d	b	(19,2)	(13,8)	(15,6)	d	c	
19	d	a	b	(14,7)	(12,9)	(19,2)	c	d	
20	d	a	c	(14,7)	(12,9)	(13,8)	a	a	
21	d	b	a	(13,8)	(12,9)	(13,8)	b	b	
22	d	b	c	(13,8)	(12,9)	(13,8)	a	a	
23	d	c	a	(13,8)	(12,9)	(13,8)	b	b	
24	d	c	b	(15,6)	(12,9)	(19,2)	c	d	

3.2. Example 2

Example 2:

3 voters $a \succ_v c \succ_v d \succ_v b$
 9 voters $b \succ_v a \succ_v c \succ_v d$
 8 voters $c \succ_v d \succ_v a \succ_v b$
 5 voters $d \succ_v a \succ_v b \succ_v c$
 5 voters $d \succ_v b \succ_v c \succ_v a$

$N[i,j] \in \mathbb{N}_0$ is the number of voters who strictly prefer alternative $i \in A$ to alternative $j \in A \setminus \{i\}$. In example 2, the pairwise matrix N looks as follows:

	$N[*,a]$	$N[*,b]$	$N[*,c]$	$N[*,d]$
$N[a,*]$	---	16	17	12
$N[b,*]$	14	---	19	9
$N[c,*]$	13	11	---	20
$N[d,*]$	18	21	10	---

The following digraph illustrates the graph theoretic interpretation of pairwise elections. If $N[i,j] > N[j,i]$, then there is a link from vertex i to vertex j of strength $(N[i,j], N[j,i])$:

The above digraph can be used to determine the strengths of the strongest paths. In the following, “ $x, (Z_1, Z_2), y$ ” means “ $(N[x, y], N[y, x]) = (Z_1, Z_2)$ ”.

$a \rightarrow b$: There are 2 paths from alternative a to alternative b .

Path 1: $a, (16, 14), b$
with a strength of $(16, 14)$.

Path 2: $a, (17, 13), c, (20, 10), d, (21, 9), b$
with a strength of $\min_D \{ (17, 13), (20, 10), (21, 9) \} \approx_D (17, 13)$.

So the strength of the strongest path from alternative a to alternative b is $\max_D \{ (16, 14), (17, 13) \} \approx_D (17, 13)$.

$a \rightarrow c$: There are 2 paths from alternative a to alternative c .

Path 1: $a, (16, 14), b, (19, 11), c$
with a strength of $\min_D \{ (16, 14), (19, 11) \} \approx_D (16, 14)$.

Path 2: $a, (17, 13), c$
with a strength of $(17, 13)$.

So the strength of the strongest path from alternative a to alternative c is $\max_D \{ (16, 14), (17, 13) \} \approx_D (17, 13)$.

$a \rightarrow d$: There are 2 paths from alternative a to alternative d .

Path 1: $a, (16, 14), b, (19, 11), c, (20, 10), d$
with a strength of $\min_D \{ (16, 14), (19, 11), (20, 10) \} \approx_D (16, 14)$.

Path 2: $a, (17, 13), c, (20, 10), d$
with a strength of $\min_D \{ (17, 13), (20, 10) \} \approx_D (17, 13)$.

So the strength of the strongest path from alternative a to alternative d is $\max_D \{ (16, 14), (17, 13) \} \approx_D (17, 13)$.

$b \rightarrow a$: There is only one path from alternative b to alternative a .

Path 1: $b, (19, 11), c, (20, 10), d, (18, 12), a$
with a strength of $\min_D \{ (19, 11), (20, 10), (18, 12) \} \approx_D (18, 12)$.

So the strength of the strongest path from alternative b to alternative a is $(18, 12)$.

$b \rightarrow c$: There is only one path from alternative b to alternative c .

Path 1: $b, (19,11), c$
with a strength of $(19,11)$.

So the strength of the strongest path from alternative b to alternative c is $(19,11)$.

$b \rightarrow d$: There is only one path from alternative b to alternative d .

Path 1: $b, (19,11), c, (20,10), d$
with a strength of $\min_D \{ (19,11), (20,10) \} \approx_D (19,11)$.

So the strength of the strongest path from alternative b to alternative d is $(19,11)$.

$c \rightarrow a$: There is only one path from alternative c to alternative a .

Path 1: $c, (20,10), d, (18,12), a$
with a strength of $\min_D \{ (20,10), (18,12) \} \approx_D (18,12)$.

So the strength of the strongest path from alternative c to alternative a is $(18,12)$.

$c \rightarrow b$: There are 2 paths from alternative c to alternative b .

Path 1: $c, (20,10), d, (21,9), b$
with a strength of $\min_D \{ (20,10), (21,9) \} \approx_D (20,10)$.

Path 2: $c, (20,10), d, (18,12), a, (16,14), b$
with a strength of $\min_D \{ (20,10), (18,12), (16,14) \} \approx_D (16,14)$.

So the strength of the strongest path from alternative c to alternative b is $\max_D \{ (20,10), (16,14) \} \approx_D (20,10)$.

$c \rightarrow d$: There is only one path from alternative c to alternative d .

Path 1: $c, (20,10), d$
with a strength of $(20,10)$.

So the strength of the strongest path from alternative c to alternative d is $(20,10)$.

$d \rightarrow a$: There is only one path from alternative d to alternative a .

Path 1: $d, (18,12), a$
with a strength of $(18,12)$.

So the strength of the strongest path from alternative d to alternative a is $(18,12)$.

$d \rightarrow b$: There are 2 paths from alternative d to alternative b .

Path 1: $d, (18,12), a, (16,14), b$
with a strength of $\min_D \{ (18,12), (16,14) \} \approx_D (16,14)$.

Path 2: $d, (21,9), b$
with a strength of $(21,9)$.

So the strength of the strongest path from alternative d to alternative b is $\max_D \{ (16,14), (21,9) \} \approx_D (21,9)$.

$d \rightarrow c$: There are 3 paths from alternative d to alternative c .

Path 1: $d, (18,12), a, (16,14), b, (19,11), c$
with a strength of $\min_D \{ (18,12), (16,14), (19,11) \} \approx_D (16,14)$.

Path 2: $d, (18,12), a, (17,13), c$
with a strength of $\min_D \{ (18,12), (17,13) \} \approx_D (17,13)$.

Path 3: $d, (21,9), b, (19,11), c$
with a strength of $\min_D \{ (21,9), (19,11) \} \approx_D (19,11)$.

So the strength of the strongest path from alternative d to alternative c is $\max_D \{ (16,14), (17,13), (19,11) \} \approx_D (19,11)$.

The following table lists the strongest paths, as determined by the Floyd-Warshall algorithm, as defined in section 2.3.1. The critical links of the strongest paths are underlined:

	... to <i>a</i>	... to <i>b</i>	... to <i>c</i>	... to <i>d</i>	... to every other alternative
from <i>a</i> ...	---	 <i>a</i> , <u>(17,13)</u> , <i>c</i> , (20,10), <i>d</i> , (21,9), <i>b</i>	 <i>a</i> , <u>(17,13)</u> , <i>c</i>	 <i>a</i> , <u>(17,13)</u> , <i>c</i> , (20,10), <i>d</i>	
from <i>b</i> ...	 <i>b</i> , <u>(19,11)</u> , <i>c</i> , (20,10), <i>d</i> , <u>(18,12)</u> , <i>a</i>	---	 <i>b</i> , <u>(19,11)</u> , <i>c</i>	 <i>b</i> , <u>(19,11)</u> , <i>c</i> , (20,10), <i>d</i>	
from <i>c</i> ...	 <i>c</i> , <u>(20,10)</u> , <i>d</i> , <u>(18,12)</u> , <i>a</i>	 <i>c</i> , <u>(20,10)</u> , <i>d</i> , (21,9), <i>b</i>	---	 <i>c</i> , <u>(20,10)</u> , <i>d</i>	
from <i>d</i> ...	 <i>d</i> , <u>(18,12)</u> , <i>a</i>	 <i>d</i> , <u>(21,9)</u> , <i>b</i>	 <i>d</i> , <u>(21,9)</u> , <i>b</i> , <u>(19,11)</u> , <i>c</i>	---	
from every other alternative ...					---

The strengths of the strongest paths are:

	$P_D[*,a]$	$P_D[*,b]$	$P_D[*,c]$	$P_D[*,d]$
$P_D[a,*]$	---	(17,13)	(17,13)	(17,13)
$P_D[b,*]$	(18,12)	---	(19,11)	(19,11)
$P_D[c,*]$	(18,12)	(20,10)	---	(20,10)
$P_D[d,*]$	(18,12)	(21,9)	(19,11)	---

We get $O = \{ba, ca, cb, cd, da, db\}$ and $S = \{c\}$.

Suppose, the strongest paths are calculated with the Floyd-Warshall algorithm, as defined in section 2.3.1. Then the following table documents the $C \cdot (C-1) \cdot (C-2) = 24$ steps of the Floyd-Warshall algorithm.

We start with

- $P_D[i,j] := (N[i,j], N[j,i])$ for all $i \in A$ and $j \in A \setminus \{i\}$.
- $pred[i,j] := i$ for all $i \in A$ and $j \in A \setminus \{i\}$.

	i	j	k	$P_D[j,k]$	$P_D[j,i]$	$P_D[i,k]$	$pred[j,k]$	$pred[i,k]$	result
1	a	b	c	(19,11)	(14,16)	(17,13)	b	a	
2	a	b	d	(9,21)	(14,16)	(12,18)	b	a	$P_D[b,d]$ is updated from (9,21) to (12,18); $pred[b,d]$ is updated from b to a .
3	a	c	b	(11,19)	(13,17)	(16,14)	c	a	$P_D[c,b]$ is updated from (11,19) to (13,17); $pred[c,b]$ is updated from c to a .
4	a	c	d	(20,10)	(13,17)	(12,18)	c	a	
5	a	d	b	(21,9)	(18,12)	(16,14)	d	a	
6	a	d	c	(10,20)	(18,12)	(17,13)	d	a	$P_D[d,c]$ is updated from (10,20) to (17,13); $pred[d,c]$ is updated from d to a .
7	b	a	c	(17,13)	(16,14)	(19,11)	a	b	
8	b	a	d	(12,18)	(16,14)	(12,18)	a	a	
9	b	c	a	(13,17)	(13,17)	(14,16)	c	b	
10	b	c	d	(20,10)	(13,17)	(12,18)	c	a	
11	b	d	a	(18,12)	(21,9)	(14,16)	d	b	
12	b	d	c	(17,13)	(21,9)	(19,11)	a	b	$P_D[d,c]$ is updated from (17,13) to (19,11); $pred[d,c]$ is updated from a to b .
13	c	a	b	(16,14)	(17,13)	(13,17)	a	a	
14	c	a	d	(12,18)	(17,13)	(20,10)	a	c	$P_D[a,d]$ is updated from (12,18) to (17,13); $pred[a,d]$ is updated from a to c .
15	c	b	a	(14,16)	(19,11)	(13,17)	b	c	
16	c	b	d	(12,18)	(19,11)	(20,10)	a	c	$P_D[b,d]$ is updated from (12,18) to (19,11); $pred[b,d]$ is updated from a to c .
17	c	d	a	(18,12)	(19,11)	(13,17)	d	c	
18	c	d	b	(21,9)	(19,11)	(13,17)	d	a	
19	d	a	b	(16,14)	(17,13)	(21,9)	a	d	$P_D[a,b]$ is updated from (16,14) to (17,13); $pred[a,b]$ is updated from a to d .
20	d	a	c	(17,13)	(17,13)	(19,11)	a	b	
21	d	b	a	(14,16)	(19,11)	(18,12)	b	d	$P_D[b,a]$ is updated from (14,16) to (18,12); $pred[b,a]$ is updated from b to d .
22	d	b	c	(19,11)	(19,11)	(19,11)	b	b	
23	d	c	a	(13,17)	(20,10)	(18,12)	c	d	$P_D[c,a]$ is updated from (13,17) to (18,12); $pred[c,a]$ is updated from c to d .
24	d	c	b	(13,17)	(20,10)	(21,9)	a	d	$P_D[c,b]$ is updated from (13,17) to (20,10); $pred[c,b]$ is updated from a to d .

3.3. Example 3

Example 3:

5 voters $a \succ_v c \succ_v b \succ_v e \succ_v d$
 5 voters $a \succ_v d \succ_v e \succ_v c \succ_v b$
 8 voters $b \succ_v e \succ_v d \succ_v a \succ_v c$
 3 voters $c \succ_v a \succ_v b \succ_v e \succ_v d$
 7 voters $c \succ_v a \succ_v e \succ_v b \succ_v d$
 2 voters $c \succ_v b \succ_v a \succ_v d \succ_v e$
 7 voters $d \succ_v c \succ_v e \succ_v b \succ_v a$
 8 voters $e \succ_v b \succ_v a \succ_v d \succ_v c$

The pairwise matrix N looks as follows:

	$N[*,a]$	$N[*,b]$	$N[*,c]$	$N[*,d]$	$N[*,e]$
$N[a,*]$	---	20	26	30	22
$N[b,*]$	25	---	16	33	18
$N[c,*]$	19	29	---	17	24
$N[d,*]$	15	12	28	---	14
$N[e,*]$	23	27	21	31	---

The corresponding digraph looks as follows:

The above digraph can be used to determine the strengths of the strongest paths. In the following, " $x, (Z_1, Z_2), y$ " means " $(N[x, y], N[y, x]) = (Z_1, Z_2)$ ".

$a \rightarrow b$: There are 4 paths from alternative a to alternative b .

Path 1: $a, (26,19), c, (29,16), b$
with a strength of $\min_D \{ (26,19), (29,16) \} \approx_D (26,19)$.

Path 2: $a, (26,19), c, (24,21), e, (27,18), b$
with a strength of $\min_D \{ (26,19), (24,21), (27,18) \} \approx_D (24,21)$.

Path 3: $a, (30,15), d, (28,17), c, (29,16), b$
 with a strength of $\min_D \{ (30,15), (28,17), (29,16) \} \approx_D (28,17)$.

Path 4: $a, (30,15), d, (28,17), c, (24,21), e, (27,18), b$
 with a strength of $\min_D \{ (30,15), (28,17), (24,21), (27,18) \} \approx_D (24,21)$.

So the strength of the strongest path from alternative a to alternative b is $\max_D \{ (26,19), (24,21), (28,17), (24,21) \} \approx_D (28,17)$.

$a \rightarrow c$: There are 2 paths from alternative a to alternative c .

Path 1: $a, (26,19), c$
with a strength of $(26,19)$.

Path 2: $a, (30,15), d, (28,17), c$
with a strength of $\min_D \{ (30,15), (28,17) \} \approx_D (28,17)$.

So the strength of the strongest path from alternative a to alternative c is $\max_D \{ (26,19), (28,17) \} \approx_D (28,17)$.

$a \rightarrow d$: There are 4 paths from alternative a to alternative d .

Path 1: $a, (26,19), c, (29,16), b, (33,12), d$
 with a strength of $\min_D \{ (26,19), (29,16), (33,12) \} \approx_D (26,19)$.

Path 2: $a, (26,19), c, (24,21), e, (27,18), b, (33,12), d$
 with a strength of $\min_D \{ (26,19), (24,21), (27,18), (33,12) \} \approx_D (24,21)$.

Path 3: $a, (26,19), c, (24,21), e, (31,14), d$
 with a strength of $\min_D \{ (26,19), (24,21), (31,14) \} \approx_D (24,21)$.

Path 4: $a, (30,15), d$
 with a strength of $(30,15)$.

So the strength of the strongest path from alternative a to alternative d is $\max_D \{ (26,19), (24,21), (24,21), (30,15) \} \approx_D (30,15)$.

$a \rightarrow e$: There are 2 paths from alternative a to alternative e .

Path 1: $a, (26,19), c, (24,21), e$
 with a strength of $\min_D \{ (26,19), (24,21) \} \approx_D (24,21)$.

Path 2: $a, (30,15), d, (28,17), c, (24,21), e$
 with a strength of $\min_D \{ (30,15), (28,17), (24,21) \} \approx_D (24,21)$.

So the strength of the strongest path from alternative a to alternative e is $\max_D \{ (24,21), (24,21) \} \approx_D (24,21)$.

$b \rightarrow a$: There are 2 paths from alternative b to alternative a .

Path 1: $b, (25,20), a$
with a strength of $(25,20)$.

Path 2: $b, (33,12), d, (28,17), c, (24,21), e, (23,22), a$
with a strength of $\min_D \{ (33,12), (28,17), (24,21), (23,22) \} \approx_D (23,22)$.

So the strength of the strongest path from alternative b to alternative a is $\max_D \{ (25,20), (23,22) \} \approx_D (25,20)$.

$b \rightarrow c$: There are 3 paths from alternative b to alternative c .

Path 1: $b, (25,20), a, (26,19), c$
 with a strength of $\min_D \{ (25,20), (26,19) \} \approx_D (25,20)$.

Path 2: $b, (25,20), a, (30,15), d, (28,17), c$
 with a strength of $\min_D \{ (25,20), (30,15), (28,17) \} \approx_D (25,20)$.

Path 3: $b, (33,12), d, (28,17), c$
 with a strength of $\min_D \{ (33,12), (28,17) \} \approx_D (28,17)$.

So the strength of the strongest path from alternative b to alternative c is $\max_D \{ (25,20), (25,20), (28,17) \} \approx_D (28,17)$.

$b \rightarrow d$: There are 3 paths from alternative b to alternative d .

Path 1: $b, (25,20), a, (26,19), c, (24,21), e, (31,14), d$
 with a strength of $\min_D \{ (25,20), (26,19), (24,21), (31,14) \} \approx_D (24,21)$.

Path 2: $b, (25,20), a, (30,15), d$
with a strength of $\min_D \{ (25,20), (30,15) \} \approx_D (25,20)$.

Path 3: $b, (33,12), d$
with a strength of $(33,12)$.

So the strength of the strongest path from alternative b to alternative d is $\max_D \{ (24,21), (25,20), (33,12) \} \approx_D (33,12)$.

$b \rightarrow e$: There are 3 paths from alternative b to alternative e .

Path 1: $b, (25,20), a, (26,19), c, (24,21), e$
 with a strength of $\min_D \{ (25,20), (26,19), (24,21) \} \approx_D (24,21)$.

Path 2: $b, (25,20), a, (30,15), d, (28,17), c, (24,21), e$
 with a strength of $\min_D \{ (25,20), (30,15), (28,17), (24,21) \} \approx_D (24,21)$.

Path 3: $b, (33,12), d, (28,17), c, (24,21), e$
 with a strength of $\min_D \{ (33,12), (28,17), (24,21) \} \approx_D (24,21)$.

So the strength of the strongest path from alternative b to alternative e is $\max_D \{ (24,21), (24,21), (24,21) \} \approx_D (24,21)$.

$c \rightarrow a$: There are 3 paths from alternative c to alternative a .

Path 1: $c, (29,16), b, (25,20), a$
 with a strength of $\min_D \{ (29,16), (25,20) \} \approx_D (25,20)$.

Path 2: $c, (24,21), e, (23,22), a$
 with a strength of $\min_D \{ (24,21), (23,22) \} \approx_D (23,22)$.

Path 3: $c, (24,21), e, (27,18), b, (25,20), a$
 with a strength of $\min_D \{ (24,21), (27,18), (25,20) \} \approx_D (24,21)$.

So the strength of the strongest path from alternative c to alternative a is $\max_D \{ (25,20), (23,22), (24,21) \} \approx_D (25,20)$.

$c \rightarrow b$: There are 2 paths from alternative c to alternative b .

Path 1: $c, (29,16), b$
with a strength of $(29,16)$.

Path 2: $c, (24,21), e, (27,18), b$
with a strength of $\min_D \{ (24,21), (27,18) \} \approx_D (24,21)$.

So the strength of the strongest path from alternative c to alternative b is $\max_D \{ (29,16), (24,21) \} \approx_D (29,16)$.

$c \rightarrow d$: There are 6 paths from alternative c to alternative d .

Path 1: $c, (29,16), b, (25,20), a, (30,15), d$
 with a strength of $\min_D \{ (29,16), (25,20), (30,15) \} \approx_D (25,20)$.

Path 2: $c, (29,16), b, (33,12), d$
 with a strength of $\min_D \{ (29,16), (33,12) \} \approx_D (29,16)$.

Path 3: $c, (24,21), e, (23,22), a, (30,15), d$
 with a strength of $\min_D \{ (24,21), (23,22), (30,15) \} \approx_D (23,22)$.

Path 4: $c, (24,21), e, (27,18), b, (25,20), a, (30,15), d$
 with a strength of $\min_D \{ (24,21), (27,18), (25,20), (30,15) \} \approx_D (24,21)$.

Path 5: $c, (24,21), e, (27,18), b, (33,12), d$
 with a strength of $\min_D \{ (24,21), (27,18), (33,12) \} \approx_D (24,21)$.

Path 6: $c, (24,21), e, (31,14), d$
 with a strength of $\min_D \{ (24,21), (31,14) \} \approx_D (24,21)$.

So the strength of the strongest path from alternative c to alternative d is $\max_D \{ (25,20), (29,16), (23,22), (24,21), (24,21), (24,21) \} \approx_D (29,16)$.

$c \rightarrow e$: There is only one path from alternative c to alternative e .

Path 1: $c, (24,21), e$
with a strength of $(24,21)$.

So the strength of the strongest path from alternative c to alternative e is $(24,21)$.

$d \rightarrow a$: There are 3 paths from alternative d to alternative a .

Path 1: $d, (28,17), c, (29,16), b, (25,20), a$
with a strength of $\min_D \{ (28,17), (29,16), (25,20) \} \approx_D (25,20)$.

Path 2: $d, (28,17), c, (24,21), e, (23,22), a$
 with a strength of $\min_D \{ (28,17), (24,21), (23,22) \} \approx_D (23,22)$.

Path 3: $d, (28,17), c, (24,21), e, (27,18), b, (25,20), a$
 with a strength of $\min_D \{ (28,17), (24,21), (27,18), (25,20) \} \approx_D (24,21)$.

So the strength of the strongest path from alternative d to alternative a is $\max_D \{ (25,20), (23,22), (24,21) \} \approx_D (25,20)$.

$d \rightarrow b$: There are 2 paths from alternative d to alternative b .

Path 1: $d, (28,17), c, (29,16), b$
 with a strength of $\min_D \{ (28,17), (29,16) \} \approx_D (28,17)$.

Path 2: $d, (28,17), c, (24,21), e, (27,18), b$
 with a strength of $\min_D \{ (28,17), (24,21), (27,18) \} \approx_D (24,21)$.

So the strength of the strongest path from alternative d to alternative b is $\max_D \{ (28,17), (24,21) \} \approx_D (28,17)$.

$d \rightarrow c$: There is only one path from alternative d to alternative c .

Path 1: $d, (28,17), c$
with a strength of $(28,17)$.

So the strength of the strongest path from alternative d to alternative c is $(28,17)$.

$d \rightarrow e$: There is only one path from alternative d to alternative e .

Path 1: $d, (28,17), c, (24,21), e$
with a strength of $\min_D \{ (28,17), (24,21) \} \approx_D (24,21)$.

So the strength of the strongest path from alternative d to alternative e is $(24,21)$.

$e \rightarrow a$: There are 3 paths from alternative e to alternative a .

Path 1: $e, (23,22), a$
with a strength of $(23,22)$.

Path 2: $e, (27,18), b, (25,20), a$
with a strength of $\min_D \{ (27,18), (25,20) \} \approx_D (25,20)$.

Path 3: $e, (31,14), d, (28,17), c, (29,16), b, (25,20), a$
 with a strength of $\min_D \{ (31,14), (28,17), (29,16), (25,20) \} \approx_D (25,20)$.

So the strength of the strongest path from alternative e to alternative a is $\max_D \{ (23,22), (25,20), (25,20) \} \approx_D (25,20)$.

$e \rightarrow b$: There are 4 paths from alternative e to alternative b .

Path 1: $e, (23,22), a, (26,19), c, (29,16), b$
 with a strength of $\min_D \{ (23,22), (26,19), (29,16) \} \approx_D (23,22)$.

Path 2: $e, (23,22), a, (30,15), d, (28,17), c, (29,16), b$
 with a strength of $\min_D \{ (23,22), (30,15), (28,17), (29,16) \} \approx_D (23,22)$.

Path 3: $e, (27,18), b$
 with a strength of $(27,18)$.

Path 4: $e, (31,14), d, (28,17), c, (29,16), b$
 with a strength of $\min_D \{ (31,14), (28,17), (29,16) \} \approx_D (28,17)$.

So the strength of the strongest path from alternative e to alternative b is $\max_D \{ (23,22), (23,22), (27,18), (28,17) \} \approx_D (28,17)$.

$e \rightarrow c$: There are 6 paths from alternative e to alternative c .

Path 1: $e, (23,22), a, (26,19), c$
 with a strength of $\min_D \{ (23,22), (26,19) \} \approx_D (23,22)$.

Path 2: $e, (23,22), a, (30,15), d, (28,17), c$
 with a strength of $\min_D \{ (23,22), (30,15), (28,17) \} \approx_D (23,22)$.

Path 3: $e, (27,18), b, (25,20), a, (26,19), c$
 with a strength of $\min_D \{ (27,18), (25,20), (26,19) \} \approx_D (25,20)$.

Path 4: $e, (27,18), b, (25,20), a, (30,15), d, (28,17), c$
 with a strength of $\min_D \{ (27,18), (25,20), (30,15), (28,17) \} \approx_D (25,20)$.

Path 5: $e, (27,18), b, (33,12), d, (28,17), c$
 with a strength of $\min_D \{ (27,18), (33,12), (28,17) \} \approx_D (27,18)$.

Path 6: $e, (31,14), d, (28,17), c$
 with a strength of $\min_D \{ (31,14), (28,17) \} \approx_D (28,17)$.

So the strength of the strongest path from alternative e to alternative c is $\max_D \{ (23,22), (23,22), (25,20), (25,20), (27,18), (28,17) \} \approx_D (28,17)$.

$e \rightarrow d$: There are 5 paths from alternative e to alternative d .

Path 1: $e, (23,22), a, (26,19), c, (29,16), b, (33,12), d$
 with a strength of $\min_D \{ (23,22), (26,19), (29,16), (33,12) \} \approx_D (23,22)$.

Path 2: $e, (23,22), a, (30,15), d$
 with a strength of $\min_D \{ (23,22), (30,15) \} \approx_D (23,22)$.

Path 3: $e, (27,18), b, (25,20), a, (30,15), d$
 with a strength of $\min_D \{ (27,18), (25,20), (30,15) \} \approx_D (25,20)$.

Path 4: $e, (27,18), b, (33,12), d$
 with a strength of $\min_D \{ (27,18), (33,12) \} \approx_D (27,18)$.

Path 5: $e, (31,14), d$
 with a strength of $(31,14)$.

So the strength of the strongest path from alternative e to alternative d is $\max_D \{ (23,22), (23,22), (25,20), (27,18), (31,14) \} \approx_D (31,14)$.

The following table lists the strongest paths, as determined by the Floyd-Warshall algorithm, as defined in section 2.3.1. The critical links of the strongest paths are underlined:

	... to <i>a</i>	... to <i>b</i>	... to <i>c</i>	... to <i>d</i>	... to <i>e</i>
from <i>a</i> ...	---	<i>a</i> , (30,15), <i>d</i> , <u>(28,17)</u> , <i>c</i> , (29,16), <i>b</i>	<i>a</i> , (30,15), <i>d</i> , <u>(28,17)</u> , <i>c</i>	<i>a</i> , <u>(30,15)</u> , <i>d</i>	<i>a</i> , (30,15), <i>d</i> , (28,17), <i>c</i> , <u>(24,21)</u> , <i>e</i>
from <i>b</i> ...	<i>b</i> , <u>(25,20)</u> , <i>a</i>	---	<i>b</i> , (33,12), <i>d</i> , <u>(28,17)</u> , <i>c</i>	<i>b</i> , <u>(33,12)</u> , <i>d</i>	<i>b</i> , (33,12), <i>d</i> , (28,17), <i>c</i> , <u>(24,21)</u> , <i>e</i>
from <i>c</i> ...	<i>c</i> , (29,16), <i>b</i> , <u>(25,20)</u> , <i>a</i>	<i>c</i> , <u>(29,16)</u> , <i>b</i>	---	<i>c</i> , <u>(29,16)</u> , <i>b</i> , (33,12), <i>d</i>	<i>c</i> , <u>(24,21)</u> , <i>e</i>
from <i>d</i> ...	<i>d</i> , (28,17), <i>c</i> , (29,16), <i>b</i> , <u>(25,20)</u> , <i>a</i>	<i>d</i> , <u>(28,17)</u> , <i>c</i> , (29,16), <i>b</i>	<i>d</i> , <u>(28,17)</u> , <i>c</i>	---	<i>d</i> , (28,17), <i>c</i> , <u>(24,21)</u> , <i>e</i>
from <i>e</i> ...	<i>e</i> , (31,14), <i>d</i> , (28,17), <i>c</i> , (29,16), <i>b</i> , <u>(25,20)</u> , <i>a</i>	<i>e</i> , (31,14), <i>d</i> , <u>(28,17)</u> , <i>c</i> , (29,16), <i>b</i>	<i>e</i> , (31,14), <i>d</i> , <u>(28,17)</u> , <i>c</i>	<i>e</i> , <u>(31,14)</u> , <i>d</i>	---

The strongest path from a to b is:
 a , (30,15), d , (28,17), c , (29,16), b

The strongest path from a to c is:
 a , (30,15), d , (28,17), c

The strongest path from a to d is:
 a , (30,15), d

The strongest path from a to e is:
 a , (30,15), d , (28,17), c , (24,21), e

These are the strongest paths
 from a to every other alternative.

The strongest path from b to a is:
 $b, \underline{(25,20)}, a$

The strongest path from b to c is:
 $b, (33,12), d, \underline{(28,17)}, c$

The strongest path from b to d is:
 $b, \underline{(33,12)}, d$

The strongest path from b to e is:
 $b, (33,12), d, (28,17), c, \underline{(24,21)}, e$

These are the strongest paths
 from b to every other alternative.

The strongest path from c to a is:
 c , (29,16), b , (25,20), a

The strongest path from c to b is:
 c , (29,16), b

The strongest path from c to d is:
 c , (29,16), b , (33,12), d

The strongest path from c to e is:
 c , (24,21), e

These are the strongest paths
 from c to every other alternative.

The strongest path from d to a is:
 d , $(28,17)$, c , $(29,16)$, b , $(25,20)$, a

The strongest path from d to b is:
 d , $(28,17)$, c , $(29,16)$, b

The strongest path from d to c is:
 d , $(28,17)$, c

The strongest path from d to e is:
 d , $(28,17)$, c , $(24,21)$, e

These are the strongest paths
 from d to every other alternative.

The strongest path from e to a is:
 e , (31,14), d , (28,17), c ,
 (29,16), b , (25,20), a

The strongest path from e to b is:
 e , (31,14), d , (28,17), c , (29,16), b

The strongest path from e to c is:
 e , (31,14), d , (28,17), c

The strongest path from e to d is:
 e , (31,14), d

These are the strongest paths
 from e to every other alternative.

These are the strongest paths from every other alternative to *a*.

These are the strongest paths from every other alternative to *b*.

These are the strongest paths from every other alternative to *c*.

These are the strongest paths from every other alternative to *d*.

These are the strongest paths from every other alternative to *e*.

Therefore, the strengths of the strongest paths are:

	$P_D[*,a]$	$P_D[*,b]$	$P_D[*,c]$	$P_D[*,d]$	$P_D[*,e]$
$P_D[a,*]$	---	(28,17)	(28,17)	(30,15)	(24,21)
$P_D[b,*]$	(25,20)	---	(28,17)	(33,12)	(24,21)
$P_D[c,*]$	(25,20)	(29,16)	---	(29,16)	(24,21)
$P_D[d,*]$	(25,20)	(28,17)	(28,17)	---	(24,21)
$P_D[e,*]$	(25,20)	(28,17)	(28,17)	(31,14)	---

We get $O = \{ab, ac, ad, bd, cb, cd, ea, eb, ec, ed\}$ and $S = \{e\}$.

Suppose, the strongest paths are calculated with the Floyd-Warshall algorithm, as defined in section 2.3.1. Then the following table documents the $C \cdot (C-1) \cdot (C-2) = 60$ steps of the Floyd-Warshall algorithm.

We start with

- $P_D[i,j] := (N[i,j], N[j,i])$ for all $i \in A$ and $j \in A \setminus \{i\}$.
- $pred[i,j] := i$ for all $i \in A$ and $j \in A \setminus \{i\}$.

	i	j	k	$P_D[j,k]$	$P_D[j,i]$	$P_D[i,k]$	$pred[j,k]$	$pred[i,k]$	result
1	a	b	c	(16,29)	(25,20)	(26,19)	b	a	$P_D[b,c]$ is updated from (16,29) to (25,20); $pred[b,c]$ is updated from b to a .
2	a	b	d	(33,12)	(25,20)	(30,15)	b	a	
3	a	b	e	(18,27)	(25,20)	(22,23)	b	a	$P_D[b,e]$ is updated from (18,27) to (22,23); $pred[b,e]$ is updated from b to a .
4	a	c	b	(29,16)	(19,26)	(20,25)	c	a	
5	a	c	d	(17,28)	(19,26)	(30,15)	c	a	$P_D[c,d]$ is updated from (17,28) to (19,26); $pred[c,d]$ is updated from c to a .
6	a	c	e	(24,21)	(19,26)	(22,23)	c	a	
7	a	d	b	(12,33)	(15,30)	(20,25)	d	a	$P_D[d,b]$ is updated from (12,33) to (15,30); $pred[d,b]$ is updated from d to a .
8	a	d	c	(28,17)	(15,30)	(26,19)	d	a	
9	a	d	e	(14,31)	(15,30)	(22,23)	d	a	$P_D[d,e]$ is updated from (14,31) to (15,30); $pred[d,e]$ is updated from d to a .
10	a	e	b	(27,18)	(23,22)	(20,25)	e	a	
11	a	e	c	(21,24)	(23,22)	(26,19)	e	a	$P_D[e,c]$ is updated from (21,24) to (23,22); $pred[e,c]$ is updated from e to a .
12	a	e	d	(31,14)	(23,22)	(30,15)	e	a	
13	b	a	c	(26,19)	(20,25)	(25,20)	a	a	
14	b	a	d	(30,15)	(20,25)	(33,12)	a	b	
15	b	a	e	(22,23)	(20,25)	(22,23)	a	a	
16	b	c	a	(19,26)	(29,16)	(25,20)	c	b	$P_D[c,a]$ is updated from (19,26) to (25,20); $pred[c,a]$ is updated from c to b .
17	b	c	d	(19,26)	(29,16)	(33,12)	a	b	$P_D[c,d]$ is updated from (19,26) to (29,16); $pred[c,d]$ is updated from a to b .
18	b	c	e	(24,21)	(29,16)	(22,23)	c	a	
19	b	d	a	(15,30)	(15,30)	(25,20)	d	b	
20	b	d	c	(28,17)	(15,30)	(25,20)	d	a	
21	b	d	e	(15,30)	(15,30)	(22,23)	a	a	
22	b	e	a	(23,22)	(27,18)	(25,20)	e	b	$P_D[e,a]$ is updated from (23,22) to (25,20); $pred[e,a]$ is updated from e to b .
23	b	e	c	(23,22)	(27,18)	(25,20)	a	a	$P_D[e,c]$ is updated from (23,22) to (25,20)
24	b	e	d	(31,14)	(27,18)	(33,12)	e	b	
25	c	a	b	(20,25)	(26,19)	(29,16)	a	c	$P_D[a,b]$ is updated from (20,25) to (26,19); $pred[a,b]$ is updated from a to c .
26	c	a	d	(30,15)	(26,19)	(29,16)	a	b	
27	c	a	e	(22,23)	(26,19)	(24,21)	a	c	$P_D[a,e]$ is updated from (22,23) to (24,21); $pred[a,e]$ is updated from a to c .
28	c	b	a	(25,20)	(25,20)	(25,20)	b	b	
29	c	b	d	(33,12)	(25,20)	(29,16)	b	b	
30	c	b	e	(22,23)	(25,20)	(24,21)	a	c	$P_D[b,e]$ is updated from (22,23) to (24,21); $pred[b,e]$ is updated from a to c .

	i	j	k	$P_D[j,k]$	$P_D[j,i]$	$P_D[i,k]$	$pred[j,k]$	$pred[i,k]$	result
31	c	d	a	(15,30)	(28,17)	(25,20)	d	b	$P_D[d,a]$ is updated from (15,30) to (25,20); $pred[d,a]$ is updated from d to b .
32	c	d	b	(15,30)	(28,17)	(29,16)	a	c	$P_D[d,b]$ is updated from (15,30) to (28,17); $pred[d,b]$ is updated from a to c .
33	c	d	e	(15,30)	(28,17)	(24,21)	a	c	$P_D[d,e]$ is updated from (15,30) to (24,21); $pred[d,e]$ is updated from a to c .
34	c	e	a	(25,20)	(25,20)	(25,20)	b	b

58	e	d	a	(25,20)	(24,21)	(25,20)	b	b	
59	e	d	b	(28,17)	(24,21)	(28,17)	c	c	
60	e	d	c	(28,17)	(24,21)	(28,17)	d	d	

3.4. Example 4

The following example is by Hoag and Hallett (1926, page 502), where the authors use this example to illustrate their proposal (*Hallett count*).

Example 4:

3 voters $a \succ_v b \succ_v c \succ_v d$
2 voters $c \succ_v b \succ_v d \succ_v a$
2 voters $d \succ_v a \succ_v b \succ_v c$
2 voters $d \succ_v b \succ_v c \succ_v a$

The pairwise matrix N looks as follows:

	$N[*,a]$	$N[*,b]$	$N[*,c]$	$N[*,d]$
$N[a,*]$	---	5	5	3
$N[b,*]$	4	---	7	5
$N[c,*]$	4	2	---	5
$N[d,*]$	6	4	4	---

The corresponding digraph looks as follows:

The following table lists the strongest paths, as determined by the Floyd-Warshall algorithm, as defined in section 2.3.1. The critical links of the strongest paths are underlined:

	... to <i>a</i>	... to <i>b</i>	... to <i>c</i>	... to <i>d</i>	... to every other alternative
from <i>a</i> ...	---	 <i>a</i> , <u>(5,4)</u> , <i>b</i>	 <i>a</i> , <u>(5,4)</u> , <i>c</i>	 <i>a</i> , <u>(5,4)</u> , <i>b</i> , <u>(5,4)</u> , <i>d</i>	
from <i>b</i> ...	 <i>b</i> , <u>(5,4)</u> , <i>d</i> , <u>(6,3)</u> , <i>a</i>	---	 <i>b</i> , <u>(7,2)</u> , <i>c</i>	 <i>b</i> , <u>(5,4)</u> , <i>d</i>	
from <i>c</i> ...	 <i>c</i> , <u>(5,4)</u> , <i>d</i> , <u>(6,3)</u> , <i>a</i>	 <i>c</i> , <u>(5,4)</u> , <i>d</i> , <u>(6,3)</u> , <i>a</i> , <u>(5,4)</u> , <i>b</i>	---	 <i>c</i> , <u>(5,4)</u> , <i>d</i>	
from <i>d</i> ...	 <i>d</i> , <u>(6,3)</u> , <i>a</i>	 <i>d</i> , <u>(6,3)</u> , <i>a</i> , <u>(5,4)</u> , <i>b</i>	 <i>d</i> , <u>(6,3)</u> , <i>a</i> , <u>(5,4)</u> , <i>c</i>	---	
from every other alternative ...					---

Therefore, the strengths of the strongest paths are:

	$P_D[*,a]$	$P_D[*,b]$	$P_D[*,c]$	$P_D[*,d]$
$P_D[a,*]$	---	(5,4)	(5,4)	(5,4)
$P_D[b,*]$	(5,4)	---	(7,2)	(5,4)
$P_D[c,*]$	(5,4)	(5,4)	---	(5,4)
$P_D[d,*]$	(6,3)	(5,4)	(5,4)	---

We get $O = \{bc, da\}$ and $S = \{b, d\}$.

Suppose, the strongest paths are calculated with the Floyd-Warshall algorithm, as defined in section 2.3.1. Then the following table documents the $C \cdot (C-1) \cdot (C-2) = 24$ steps of the Floyd-Warshall algorithm.

We start with

- $P_D[i,j] := (N[i,j], N[j,i])$ for all $i \in A$ and $j \in A \setminus \{i\}$.
- $pred[i,j] := i$ for all $i \in A$ and $j \in A \setminus \{i\}$.

	i	j	k	$P_D[j,k]$	$P_D[j,i]$	$P_D[i,k]$	$pred[j,k]$	$pred[i,k]$	result
1	a	b	c	(7,2)	(4,5)	(5,4)	b	a	
2	a	b	d	(5,4)	(4,5)	(3,6)	b	a	
3	a	c	b	(2,7)	(4,5)	(5,4)	c	a	$P_D[c,b]$ is updated from (2,7) to (4,5); $pred[c,b]$ is updated from c to a .
4	a	c	d	(5,4)	(4,5)	(3,6)	c	a	
5	a	d	b	(4,5)	(6,3)	(5,4)	d	a	$P_D[d,b]$ is updated from (4,5) to (5,4); $pred[d,b]$ is updated from d to a .
6	a	d	c	(4,5)	(6,3)	(5,4)	d	a	$P_D[d,c]$ is updated from (4,5) to (5,4); $pred[d,c]$ is updated from d to a .
7	b	a	c	(5,4)	(5,4)	(7,2)	a	b	
8	b	a	d	(3,6)	(5,4)	(5,4)	a	b	$P_D[a,d]$ is updated from (3,6) to (5,4); $pred[a,d]$ is updated from a to b .
9	b	c	a	(4,5)	(4,5)	(4,5)	c	b	
10	b	c	d	(5,4)	(4,5)	(5,4)	c	b	
11	b	d	a	(6,3)	(5,4)	(4,5)	d	b	
12	b	d	c	(5,4)	(5,4)	(7,2)	a	b	
13	c	a	b	(5,4)	(5,4)	(4,5)	a	a	
14	c	a	d	(5,4)	(5,4)	(5,4)	b	c	
15	c	b	a	(4,5)	(7,2)	(4,5)	b	c	
16	c	b	d	(5,4)	(7,2)	(5,4)	b	c	
17	c	d	a	(6,3)	(5,4)	(4,5)	d	c	
18	c	d	b	(5,4)	(5,4)	(4,5)	a	a	
19	d	a	b	(5,4)	(5,4)	(5,4)	a	a	
20	d	a	c	(5,4)	(5,4)	(5,4)	a	a	
21	d	b	a	(4,5)	(5,4)	(6,3)	b	d	$P_D[b,a]$ is updated from (4,5) to (5,4); $pred[b,a]$ is updated from b to d .
22	d	b	c	(7,2)	(5,4)	(5,4)	b	a	
23	d	c	a	(4,5)	(5,4)	(6,3)	c	d	$P_D[c,a]$ is updated from (4,5) to (5,4); $pred[c,a]$ is updated from c to d .
24	d	c	b	(4,5)	(5,4)	(5,4)	a	a	$P_D[c,b]$ is updated from (4,5) to (5,4).

3.5. Example 5

Example 5:

12 voters $a \succ_v b \succ_v c \succ_v d$
6 voters $a \succ_v d \succ_v b \succ_v c$
9 voters $b \succ_v c \succ_v d \succ_v a$
15 voters $c \succ_v d \succ_v a \succ_v b$
21 voters $d \succ_v b \succ_v a \succ_v c$

The pairwise matrix N looks as follows:

	$N[*,a]$	$N[*,b]$	$N[*,c]$	$N[*,d]$
$N[a,*]$	---	33	39	18
$N[b,*]$	30	---	48	21
$N[c,*]$	24	15	---	36
$N[d,*]$	45	42	27	---

The corresponding digraph looks as follows:

The following table lists the strongest paths, as determined by the Floyd-Warshall algorithm, as defined in section 2.3.1. The critical links of the strongest paths are underlined:

	... to <i>a</i>	... to <i>b</i>	... to <i>c</i>	... to <i>d</i>	... to every other alternative
from <i>a</i> ...	---	 <i>a</i> , (39,24), <i>c</i> , <u>(36,27)</u> , <i>d</i> , (42,21), <i>b</i>	 <i>a</i> , <u>(39,24)</u> , <i>c</i>	 <i>a</i> , (39,24), <i>c</i> , <u>(36,27)</u> , <i>d</i>	 <i>a</i> , (39,24), <i>c</i> , <u>(36,27)</u> , <i>d</i>
from <i>b</i> ...	 <i>b</i> , (48,15), <i>c</i> , <u>(36,27)</u> , <i>d</i> , (45,18), <i>a</i>	---	 <i>b</i> , <u>(48,15)</u> , <i>c</i>	 <i>b</i> , (48,15), <i>c</i> , <u>(36,27)</u> , <i>d</i>	 <i>b</i> , (48,15), <i>c</i> , <u>(36,27)</u> , <i>d</i>
from <i>c</i> ...	 <i>c</i> , (36,27), <i>d</i> , (45,18), <i>a</i>	 <i>c</i> , (36,27), <i>d</i> , (42,21), <i>b</i>	---	 <i>c</i> , <u>(36,27)</u> , <i>d</i>	 <i>c</i> , (36,27), <i>d</i>
from <i>d</i> ...	 <i>d</i> , (45,18), <i>a</i>	 <i>d</i> , <u>(42,21)</u> , <i>b</i>	 <i>d</i> , <u>(42,21)</u> , <i>b</i> , (48,15), <i>c</i>	---	 <i>d</i> , (45,18), <i>a</i>
from every other alternative ...	 ---	 ---	 ---	 ---	---

Therefore, the strengths of the strongest paths are:

	$P_D[*,a]$	$P_D[*,b]$	$P_D[*,c]$	$P_D[*,d]$
$P_D[a,*]$	---	(36,27)	(39,24)	(36,27)
$P_D[b,*]$	(36,27)	---	(48,15)	(36,27)
$P_D[c,*]$	(36,27)	(36,27)	---	(36,27)
$P_D[d,*]$	(45,18)	(42,21)	(42,21)	---

We get $O = \{ac, bc, da, db, dc\}$ and $S = \{d\}$.

Suppose, the strongest paths are calculated with the Floyd-Warshall algorithm, as defined in section 2.3.1. Then the following table documents the $C \cdot (C-1) \cdot (C-2) = 24$ steps of the Floyd-Warshall algorithm.

We start with

- $P_D[i,j] := (N[i,j], N[j,i])$ for all $i \in A$ and $j \in A \setminus \{i\}$.
- $pred[i,j] := i$ for all $i \in A$ and $j \in A \setminus \{i\}$.

	i	j	k	$P_D[j,k]$	$P_D[j,i]$	$P_D[i,k]$	$pred[j,k]$	$pred[i,k]$	result
1	a	b	c	(48,15)	(30,33)	(39,24)	b	a	
2	a	b	d	(21,42)	(30,33)	(18,45)	b	a	
3	a	c	b	(15,48)	(24,39)	(33,30)	c	a	$P_D[c,b]$ is updated from (15,48) to (24,39); $pred[c,b]$ is updated from c to a .
4	a	c	d	(36,27)	(24,39)	(18,45)	c	a	
5	a	d	b	(42,21)	(45,18)	(33,30)	d	a	
6	a	d	c	(27,36)	(45,18)	(39,24)	d	a	$P_D[d,c]$ is updated from (27,36) to (39,24); $pred[d,c]$ is updated from d to a .
7	b	a	c	(39,24)	(33,30)	(48,15)	a	b	
8	b	a	d	(18,45)	(33,30)	(21,42)	a	b	$P_D[a,d]$ is updated from (18,45) to (21,42); $pred[a,d]$ is updated from a to b .
9	b	c	a	(24,39)	(24,39)	(30,33)	c	b	
10	b	c	d	(36,27)	(24,39)	(21,42)	c	b	
11	b	d	a	(45,18)	(42,21)	(30,33)	d	b	
12	b	d	c	(39,24)	(42,21)	(48,15)	a	b	$P_D[d,c]$ is updated from (39,24) to (42,21); $pred[d,c]$ is updated from a to b .
13	c	a	b	(33,30)	(39,24)	(24,39)	a	a	
14	c	a	d	(21,42)	(39,24)	(36,27)	b	c	$P_D[a,d]$ is updated from (21,42) to (36,27); $pred[a,d]$ is updated from b to c .
15	c	b	a	(30,33)	(48,15)	(24,39)	b	c	
16	c	b	d	(21,42)	(48,15)	(36,27)	b	c	$P_D[b,d]$ is updated from (21,42) to (36,27); $pred[b,d]$ is updated from b to c .
17	c	d	a	(45,18)	(42,21)	(24,39)	d	c	
18	c	d	b	(42,21)	(42,21)	(24,39)	d	a	
19	d	a	b	(33,30)	(36,27)	(42,21)	a	d	$P_D[a,b]$ is updated from (33,30) to (36,27); $pred[a,b]$ is updated from a to d .
20	d	a	c	(39,24)	(36,27)	(42,21)	a	b	
21	d	b	a	(30,33)	(36,27)	(45,18)	b	d	$P_D[b,a]$ is updated from (30,33) to (36,27); $pred[b,a]$ is updated from b to d .
22	d	b	c	(48,15)	(36,27)	(42,21)	b	b	
23	d	c	a	(24,39)	(36,27)	(45,18)	c	d	$P_D[c,a]$ is updated from (24,39) to (36,27); $pred[c,a]$ is updated from c to d .
24	d	c	b	(24,39)	(36,27)	(42,21)	a	d	$P_D[c,b]$ is updated from (24,39) to (36,27); $pred[c,b]$ is updated from a to d .

3.6. Example 6

Example 6:

8 voters $a \succ_v c \succ_v d \succ_v b$
2 voter $b \succ_v c \succ_v d \succ_v a$
3 voters $b \succ_v d \succ_v a \succ_v c$
5 voters $c \succ_v b \succ_v d \succ_v a$
1 voters $c \succ_v d \succ_v b \succ_v a$
3 voters $d \succ_v a \succ_v b \succ_v c$
1 voters $d \succ_v b \succ_v a \succ_v c$

The pairwise matrix N looks as follows:

	$N[*,a]$	$N[*,b]$	$N[*,c]$	$N[*,d]$
$N[a,*]$	---	11	15	8
$N[b,*]$	12	---	9	10
$N[c,*]$	8	14	---	16
$N[d,*]$	15	13	7	---

The corresponding digraph looks as follows:

The following table lists the strongest paths, as determined by the Floyd-Warshall algorithm, as defined in section 2.3.1. The critical links of the strongest paths are underlined:

	... to <i>a</i>	... to <i>b</i>	... to <i>c</i>	... to <i>d</i>	... to every other alternative
from <i>a</i> ...	---	 <i>a</i> , <u>(15,8)</u> , <i>c</i> , <u>(14,9)</u> , <i>b</i>	 <i>a</i> , <u>(15,8)</u> , <i>c</i>	 <i>a</i> , <u>(15,8)</u> , <i>c</i> , <u>(16,7)</u> , <i>d</i>	
from <i>b</i> ...	 <i>b</i> , <u>(12,11)</u> , <i>a</i>	---	 <i>b</i> , <u>(12,11)</u> , <i>a</i> , <u>(15,8)</u> , <i>c</i>	 <i>b</i> , <u>(12,11)</u> , <i>a</i> , <u>(15,8)</u> , <i>c</i> , <u>(16,7)</u> , <i>d</i>	
from <i>c</i> ...	 <i>c</i> , <u>(16,7)</u> , <i>d</i> , <u>(15,8)</u> , <i>a</i>	 <i>c</i> , <u>(14,9)</u> , <i>b</i>	---	 <i>c</i> , <u>(16,7)</u> , <i>d</i>	
from <i>d</i> ...	 <i>d</i> , <u>(15,8)</u> , <i>a</i>	 <i>d</i> , <u>(15,8)</u> , <i>a</i> , <u>(15,8)</u> , <i>c</i> , <u>(14,9)</u> , <i>b</i>	 <i>d</i> , <u>(15,8)</u> , <i>a</i> , <u>(15,8)</u> , <i>c</i>	---	
from every other alternative ...					---

Therefore, the strengths of the strongest paths are:

	$P_D[*,a]$	$P_D[*,b]$	$P_D[*,c]$	$P_D[*,d]$
$P_D[a,*]$	---	(14,9)	(15,8)	(15,8)
$P_D[b,*]$	(12,11)	---	(12,11)	(12,11)
$P_D[c,*]$	(15,8)	(14,9)	---	(16,7)
$P_D[d,*]$	(15,8)	(14,9)	(15,8)	---

We get $O = \{ab, cb, cd, db\}$ and $S = \{a, c\}$.

Suppose, the strongest paths are calculated with the Floyd-Warshall algorithm, as defined in section 2.3.1. Then the following table documents the $C \cdot (C-1) \cdot (C-2) = 24$ steps of the Floyd-Warshall algorithm.

We start with

- $P_D[i,j] := (N[i,j], N[j,i])$ for all $i \in A$ and $j \in A \setminus \{i\}$.
- $pred[i,j] := i$ for all $i \in A$ and $j \in A \setminus \{i\}$.

	i	j	k	$P_D[j,k]$	$P_D[j,i]$	$P_D[i,k]$	$pred[j,k]$	$pred[i,k]$	result
1	a	b	c	(9,14)	(12,11)	(15,8)	b	a	$P_D[b,c]$ is updated from (9,14) to (12,11); $pred[b,c]$ is updated from b to a .
2	a	b	d	(10,13)	(12,11)	(8,15)	b	a	
3	a	c	b	(14,9)	(8,15)	(11,12)	c	a	
4	a	c	d	(16,7)	(8,15)	(8,15)	c	a	
5	a	d	b	(13,10)	(15,8)	(11,12)	d	a	
6	a	d	c	(7,16)	(15,8)	(15,8)	d	a	$P_D[d,c]$ is updated from (7,16) to (15,8); $pred[d,c]$ is updated from d to a .
7	b	a	c	(15,8)	(11,12)	(12,11)	a	a	
8	b	a	d	(8,15)	(11,12)	(10,13)	a	b	$P_D[a,d]$ is updated from (8,15) to (10,13); $pred[a,d]$ is updated from a to b .
9	b	c	a	(8,15)	(14,9)	(12,11)	c	b	$P_D[c,a]$ is updated from (8,15) to (12,11); $pred[c,a]$ is updated from c to b .
10	b	c	d	(16,7)	(14,9)	(10,13)	c	b	
11	b	d	a	(15,8)	(13,10)	(12,11)	d	b	
12	b	d	c	(15,8)	(13,10)	(12,11)	a	a	
13	c	a	b	(11,12)	(15,8)	(14,9)	a	c	$P_D[a,b]$ is updated from (11,12) to (14,9); $pred[a,b]$ is updated from a to c .
14	c	a	d	(10,13)	(15,8)	(16,7)	b	c	$P_D[a,d]$ is updated from (10,13) to (15,8); $pred[a,d]$ is updated from b to c .
15	c	b	a	(12,11)	(12,11)	(12,11)	b	b	
16	c	b	d	(10,13)	(12,11)	(16,7)	b	c	$P_D[b,d]$ is updated from (10,13) to (12,11); $pred[b,d]$ is updated from b to c .
17	c	d	a	(15,8)	(15,8)	(12,11)	d	b	
18	c	d	b	(13,10)	(15,8)	(14,9)	d	c	$P_D[d,b]$ is updated from (13,10) to (14,9); $pred[d,b]$ is updated from d to c .
19	d	a	b	(14,9)	(15,8)	(14,9)	c	c	
20	d	a	c	(15,8)	(15,8)	(15,8)	a	a	
21	d	b	a	(12,11)	(12,11)	(15,8)	b	d	
22	d	b	c	(12,11)	(12,11)	(15,8)	a	a	
23	d	c	a	(12,11)	(16,7)	(15,8)	b	d	$P_D[c,a]$ is updated from (12,11) to (15,8); $pred[c,a]$ is updated from b to d .
24	d	c	b	(14,9)	(16,7)	(14,9)	c	c	

3.7. Example 7

The basic idea for the following example has been proposed by Cretney (1998).

3.7.1. Situation #1

Example 7 (old):

3 voters $a >_v d >_v e >_v b >_v c >_v f$
 3 voters $b >_v f >_v e >_v c >_v d >_v a$
 4 voters $c >_v a >_v b >_v f >_v d >_v e$
 1 voter $d >_v b >_v c >_v e >_v f >_v a$
 4 voters $d >_v e >_v f >_v a >_v b >_v c$
 2 voters $e >_v c >_v b >_v d >_v f >_v a$
 2 voters $f >_v a >_v c >_v d >_v b >_v e$

The pairwise matrix N^{old} looks as follows:

	$N^{\text{old}}[*,a]$	$N^{\text{old}}[*,b]$	$N^{\text{old}}[*,c]$	$N^{\text{old}}[*,d]$	$N^{\text{old}}[*,e]$	$N^{\text{old}}[*,f]$
$N^{\text{old}}[a,*]$	---	13	9	9	9	7
$N^{\text{old}}[b,*]$	6	---	11	9	10	13
$N^{\text{old}}[c,*]$	10	8	---	11	7	10
$N^{\text{old}}[d,*]$	10	10	8	---	14	10
$N^{\text{old}}[e,*]$	10	9	12	5	---	10
$N^{\text{old}}[f,*]$	12	6	9	9	9	---

The corresponding digraph looks as follows:

The following table lists the strongest paths, as determined by the Floyd-Warshall algorithm, as defined in section 2.3.1. The critical links of the strongest paths are underlined:

	... to <i>a</i>	... to <i>b</i>	... to <i>c</i>	... to <i>d</i>	... to <i>e</i>	... to <i>f</i>
from <i>a</i> ...	---	<i>a</i> , <u>(13,6)</u> , <i>b</i>	<i>a</i> , (13,6), <i>b</i> , <u>(11,8)</u> , <i>c</i>	<i>a</i> , (13,6), <i>b</i> , <u>(11,8)</u> , <i>c</i> , <u>(11,8)</u> , <i>d</i>	<i>a</i> , (13,6), <i>b</i> , <u>(11,8)</u> , <i>c</i> , <u>(11,8)</u> , <i>d</i> , (14,5), <i>e</i>	<i>a</i> , <u>(13,6)</u> , <i>b</i> , <u>(13,6)</u> , <i>f</i>
from <i>b</i> ...	<i>b</i> , (13,6), <i>f</i> , <u>(12,7)</u> , <i>a</i>	---	<i>b</i> , <u>(11,8)</u> , <i>c</i>	<i>b</i> , <u>(11,8)</u> , <i>c</i> , <u>(11,8)</u> , <i>d</i>	<i>b</i> , <u>(11,8)</u> , <i>c</i> , <u>(11,8)</u> , <i>d</i> , (14,5), <i>e</i>	<i>b</i> , <u>(13,6)</u> , <i>f</i>
from <i>c</i> ...	<i>c</i> , <u>(10,9)</u> , <i>a</i>	<i>c</i> , <u>(10,9)</u> , <i>a</i> , (13,6), <i>b</i>	---	<i>c</i> , <u>(11,8)</u> , <i>d</i>	<i>c</i> , <u>(11,8)</u> , <i>d</i> , (14,5), <i>e</i>	<i>c</i> , <u>(10,9)</u> , <i>f</i>
from <i>d</i> ...	<i>d</i> , <u>(10,9)</u> , <i>a</i>	<i>d</i> , <u>(10,9)</u> , <i>b</i>	<i>d</i> , (14,5), <i>e</i> , <u>(12,7)</u> , <i>c</i>	---	<i>d</i> , <u>(14,5)</u> , <i>e</i>	<i>d</i> , <u>(10,9)</u> , <i>f</i>
from <i>e</i> ...	<i>e</i> , <u>(10,9)</u> , <i>a</i>	<i>e</i> , <u>(10,9)</u> , <i>a</i> , (13,6), <i>b</i>	<i>e</i> , <u>(12,7)</u> , <i>c</i>	<i>e</i> , (12,7), <i>c</i> , <u>(11,8)</u> , <i>d</i>	---	<i>e</i> , <u>(10,9)</u> , <i>f</i>
from <i>f</i> ...	<i>f</i> , <u>(12,7)</u> , <i>a</i>	<i>f</i> , <u>(12,7)</u> , <i>a</i> , (13,6), <i>b</i>	<i>f</i> , (12,7), <i>a</i> , (13,6), <i>b</i> , <u>(11,8)</u> , <i>c</i>	<i>f</i> , (12,7), <i>a</i> , (13,6), <i>b</i> , <u>(11,8)</u> , <i>c</i> , <u>(11,8)</u> , <i>d</i>	<i>f</i> , (12,7), <i>a</i> , (13,6), <i>b</i> , <u>(11,8)</u> , <i>c</i> , <u>(11,8)</u> , <i>d</i> , (14,5), <i>e</i>	---

The strongest path from a to b is:
 $a, \underline{(13,6)}, b$

The strongest path from a to c is:
 $a, (13,6), b, \underline{(11,8)}, c$

The strongest path from a to d is:
 $a, (13,6), b, \underline{(11,8)}, c, \underline{(11,8)}, d$

The strongest path from a to e is:
 $a, (13,6), b, \underline{(11,8)}, c, \underline{(11,8)}, d, \underline{(14,5)}, e$

The strongest path from a to f is:
 $a, \underline{(13,6)}, b, \underline{(13,6)}, f$

These are the strongest paths
 from a to every other alternative.

The strongest path from b to a is:
b, (13,6), f, (12,7), a

The strongest path from b to c is:
b, (11,8), c

The strongest path from b to d is:
b, (11,8), c, (11,8), d

The strongest path from b to e is:
b, (11,8), c, (11,8), d, (14,5), e

The strongest path from b to f is:
b, (13,6), f

These are the strongest paths
from b to every other alternative.

The strongest path from c to a is:
c, (10,9), a

The strongest path from c to b is:
c, (10,9), a, (13,6), b

The strongest path from c to d is:
c, (11,8), d

The strongest path from c to e is:
c, (11,8), d, (14,5), e

The strongest path from c to f is:
c, (10,9), f

These are the strongest paths
from c to every other alternative.

The strongest path from d to a is:
 $d, (10,9), a$

The strongest path from d to b is:
 $d, (10,9), b$

The strongest path from d to c is:
 $d, (14,5), e, (12,7), c$

The strongest path from d to e is:
 $d, (14,5), e$

The strongest path from d to f is:
 $d, (10,9), f$

These are the strongest paths from d to every other alternative.

The strongest path from e to a is:
e, (10,9), a

The strongest path from e to b is:
e, (10,9), a, (13,6), b

The strongest path from e to c is:
e, (12,7), c

The strongest path from e to d is:
e, (12,7), c, (11,8), d

The strongest path from e to f is:
e, (10,9), f

These are the strongest paths
from e to every other alternative.

The strongest path from f to a is:
 $f, \underline{(12,7)}, a$

The strongest path from f to b is:
 $f, \underline{(12,7)}, a, (13,6), b$

The strongest path from f to c is:
 $f, (12,7), a, (13,6), b, \underline{(11,8)}, c$

The strongest path from f to d is:
 $f, (12,7), a, (13,6), b, \underline{(11,8)}, c, \underline{(11,8)}, d$

The strongest path from f to e is:
 $f, (12,7), a, (13,6), b, \underline{(11,8)}, c, \underline{(11,8)}, d, (14,5), e$

These are the strongest paths from f to every other alternative.

These are the strongest paths from every other alternative to a.

These are the strongest paths from every other alternative to b.

These are the strongest paths from every other alternative to c.

These are the strongest paths from every other alternative to d.

These are the strongest paths from every other alternative to e.

These are the strongest paths from every other alternative to f.

Therefore, the strengths of the strongest paths are:

	$P_D[*,a]$	$P_D[*,b]$	$P_D[*,c]$	$P_D[*,d]$	$P_D[*,e]$	$P_D[*,f]$
$P_D[a,*]$	---	(13,6)	(11,8)	(11,8)	(11,8)	(13,6)
$P_D[b,*]$	(12,7)	---	(11,8)	(11,8)	(11,8)	(13,6)
$P_D[c,*]$	(10,9)	(10,9)	---	(11,8)	(11,8)	(10,9)
$P_D[d,*]$	(10,9)	(10,9)	(12,7)	---	(14,5)	(10,9)
$P_D[e,*]$	(10,9)	(10,9)	(12,7)	(11,8)	---	(10,9)
$P_D[f,*]$	(12,7)	(12,7)	(11,8)	(11,8)	(11,8)	---

We get $\mathcal{O}^{\text{old}} = \{ab, ac, ad, ae, af, bc, bd, be, bf, dc, de, ec, fc, fd, fe\}$ and $\mathcal{S}^{\text{old}} = \{a\}$.

Suppose, the strongest paths are calculated with the Floyd-Warshall algorithm, as defined in section 2.3.1. Then the following table documents the $C \cdot (C-1) \cdot (C-2) = 120$ steps of the Floyd-Warshall algorithm.

We start with

- $P_D[i,j] := (N^{\text{old}}[i,j], N^{\text{old}}[j,i])$ for all $i \in A$ and $j \in A \setminus \{i\}$.
- $\text{pred}[i,j] := i$ for all $i \in A$ and $j \in A \setminus \{i\}$.

	i	j	k	$P_D[j,k]$	$P_D[j,i]$	$P_D[i,k]$	$pred[j,k]$	$pred[i,k]$	result
1	a	b	c	(11,8)	(6,13)	(9,10)	b	a	
2	a	b	d	(9,10)	(6,13)	(9,10)	b	a	
3	a	b	e	(10,9)	(6,13)	(9,10)	b	a	
4	a	b	f	(13,6)	(6,13)	(7,12)	b	a	
5	a	c	b	(8,11)	(10,9)	(13,6)	c	a	$P_D[c,b]$ is updated from (8,11) to (10,9); $pred[c,b]$ is updated from c to a .
6	a	c	d	(11,8)	(10,9)	(9,10)	c	a	
7	a	c	e	(7,12)	(10,9)	(9,10)	c	a	$P_D[c,e]$ is updated from (7,12) to (9,10); $pred[c,e]$ is updated from c to a .
8	a	c	f	(10,9)	(10,9)	(7,12)	c	a	
9	a	d	b	(10,9)	(10,9)	(13,6)	d	a	
10	a	d	c	(8,11)	(10,9)	(9,10)	d	a	$P_D[d,c]$ is updated from (8,11) to (9,10); $pred[d,c]$ is updated from d to a .
11	a	d	e	(14,5)	(10,9)	(9,10)	d	a	
12	a	d	f	(10,9)	(10,9)	(7,12)	d	a

3.7.2. Situation #2

When 2 $a >_v e >_v f >_v c >_v b >_v d$ ballots are added, then the pairwise matrix N^{new} looks as follows:

	$N^{\text{new}}[*,a]$	$N^{\text{new}}[*,b]$	$N^{\text{new}}[*,c]$	$N^{\text{new}}[*,d]$	$N^{\text{new}}[*,e]$	$N^{\text{new}}[*,f]$
$N^{\text{new}}[a,*]$	---	15	11	11	11	9
$N^{\text{new}}[b,*]$	6	---	11	11	10	13
$N^{\text{new}}[c,*]$	10	10	---	13	7	10
$N^{\text{new}}[d,*]$	10	10	8	---	14	10
$N^{\text{new}}[e,*]$	10	11	14	7	---	12
$N^{\text{new}}[f,*]$	12	8	11	11	9	---

The corresponding digraph looks as follows:

The following table lists the strongest paths, as determined by the Floyd-Warshall algorithm, as defined in section 2.3.1. The critical links of the strongest paths are underlined:

	... to <i>a</i>	... to <i>b</i>	... to <i>c</i>	... to <i>d</i>	... to <i>e</i>	... to <i>f</i>
from <i>a</i> ...	---	<i>a</i> , <u>(15,6)</u> , <i>b</i>	<i>a</i> , <u>(11,10)</u> , <i>c</i>	<i>a</i> , <u>(11,10)</u> , <i>d</i>	<i>a</i> , <u>(11,10)</u> , <i>e</i>	<i>a</i> , (15,6), <i>b</i> , <u>(13,8)</u> , <i>f</i>

The strongest path from a to b is:
 $a, \underline{(15,6)}, b$

The strongest path from a to c is:
 $a, \underline{(11,10)}, c$

The strongest path from a to d is:
 $a, \underline{(11,10)}, d$

The strongest path from a to e is:
 $a, \underline{(11,10)}, e$

The strongest path from a to f is:
 $a, \underline{(15,6)}, b, \underline{(13,8)}, f$

These are the strongest paths from a to every other alternative.

The strongest path from b to a is:
 $b, (13,8), f, (12,9), a$

The strongest path from b to c is:
 $b, (11,10), c$

The strongest path from b to d is:
 $b, (11,10), d$

The strongest path from b to e is:
 $b, (11,10), d, (14,7), e$

The strongest path from b to f is:
 $b, (13,8), f$

These are the strongest paths
from b to every other alternative.

The strongest path from c to a is:
 $c, (13,8), d, (14,7), e, (12,9), f, (12,9), a$

The strongest path from c to b is:
 $c, (13,8), d, (14,7), e, (12,9), f, (12,9), a, (15,6), b$

The strongest path from c to d is:
 $c, (13,8), d$

The strongest path from c to e is:
 $c, (13,8), d, (14,7), e$

The strongest path from c to f is:
 $c, (13,8), d, (14,7), e, (12,9), f$

These are the strongest paths
 from c to every other alternative.

The strongest path from d to a is:
 $d, (14,7), e, (12,9), f, (12,9), a$

The strongest path from d to b is:
 $d, (14,7), e, (12,9), f, (12,9), a, (15,6), b$

The strongest path from d to c is:
 $d, (14,7), e, (14,7), c$

The strongest path from d to e is:
 $d, (14,7), e$

The strongest path from d to f is:
 $d, (14,7), e, (12,9), f$

These are the strongest paths
from d to every other alternative.

The strongest path from e to a is:
 $e, \underline{(12,9)}, f, \underline{(12,9)}, a$

The strongest path from e to b is:
 $e, \underline{(12,9)}, f, \underline{(12,9)}, a, \underline{(15,6)}, b$

The strongest path from e to c is:
 $e, \underline{(14,7)}, c$

The strongest path from e to d is:
 $e, \underline{(14,7)}, c, \underline{(13,8)}, d$

The strongest path from e to f is:
 $e, \underline{(12,9)}, f$

These are the strongest paths from e to every other alternative.

The strongest path from f to a is:
 $f, (12,9), a$

The strongest path from f to b is:
 $f, (12,9), a, (15,6), b$

The strongest path from f to c is:
 $f, (11,10), c$

The strongest path from f to d is:
 $f, (11,10), d$

The strongest path from f to e is:
 $f, (12,9), a, (11,10), e$

These are the strongest paths from f to every other alternative.

These are the strongest paths from every other alternative to a.

These are the strongest paths from every other alternative to b.

These are the strongest paths from every other alternative to c.

These are the strongest paths from every other alternative to d.

These are the strongest paths from every other alternative to e.

These are the strongest paths from every other alternative to f.

Therefore, the strengths of the strongest paths are:

	$P_D[*,a]$	$P_D[*,b]$	$P_D[*,c]$	$P_D[*,d]$	$P_D[*,e]$	$P_D[*,f]$
$P_D[a,*]$	---	(15,6)	(11,10)	(11,10)	(11,10)	(13,8)
$P_D[b,*]$	(12,9)	---	(11,10)	(11,10)	(11,10)	(13,8)
$P_D[c,*]$	(12,9)	(12,9)	---	(13,8)	(13,8)	(12,9)
$P_D[d,*]$	(12,9)	(12,9)	(14,7)	---	(14,7)	(12,9)
$P_D[e,*]$	(12,9)	(12,9)	(14,7)	(13,8)	---	(12,9)
$P_D[f,*]$	(12,9)	(12,9)	(11,10)	(11,10)	(11,10)	---

We get $O^{\text{new}} = \{ab, af, bf, ca, cb, cf, da, db, dc, de, df, ea, eb, ec, ef\}$ and $S^{\text{new}} = \{d\}$.

Thus the 2 $a >_v e >_v f >_v c >_v b >_v d$ voters change the unique winner from alternative a to alternative d .

Suppose, the strongest paths are calculated with the Floyd-Warshall algorithm, as defined in section 2.3.1. Then the following table documents the $C \cdot (C-1) \cdot (C-2) = 120$ steps of the Floyd-Warshall algorithm.

We start with

- $P_D[i,j] := (N^{\text{new}}[i,j], N^{\text{new}}[j,i])$ for all $i \in A$ and $j \in A \setminus \{i\}$.
- $\text{pred}[i,j] := i$ for all $i \in A$ and $j \in A \setminus \{i\}$.

	i	j	k	$P_D[j,k]$	$P_D[j,i]$	$P_D[i,k]$	$pred[j,k]$	$pred[i,k]$	result
1	a	b	c	(11,10)	(6,15)	(11,10)	b	a	
2	a	b	d	(11,10)	(6,15)	(11,10)	b	a	
3	a	b	e	(10,11)	(6,15)	(11,10)	b	a	
4	a	b	f	(13,8)	(6,15)	(9,12)	b	a	
5	a	c	b	(10,11)	(10,11)	(15,6)	c	a	
6	a	c	d	(13,8)	(10,11)	(11,10)	c	a	
7	a	c	e	(7,14)	(10,11)	(11,10)	c	a	$P_D[c,e]$ is updated from (7,14) to (10,11); $pred[c,e]$ is updated from c to a .
8	a	c	f	(10,11)	(10,11)	(9,12)	c	a	
9	a	d	b	(10,11)	(10,11)	(15,6)	d	a	
10	a	d	c	(8,13)	(10,11)	(11,10)	d	a	$P_D[d,c]$ is updated from (8,13) to (10,11); $pred[d,c]$ is updated from d to a .
11	a	d	e	(14,7)	(10,11)	(11,10)	d	a

3.8. Example 8

Independence from Pareto-dominated alternatives (IPDA) as a criterion for single-winner election methods has been proposed by Fishburn (1973). This criterion is also called *reduction* (Fishburn, 1973; Richelson, 1978).

When $i \succsim_v j$ for every $v \in V$, then we say “alternative i Pareto-dominates alternative j ”.

Suppose an alternative j is added such that:

$$(3.8.1) \quad \exists i \in A^{\text{old}} \forall v \in V: i \succsim_v^{\text{new}} j.$$

$$(3.8.2) \quad \forall g, h \in A^{\text{old}} \forall v \in V: g \succ_v^{\text{old}} h \Leftrightarrow g \succ_v^{\text{new}} h.$$

Then *independence from Pareto-dominated alternatives* says that we must get:

$$(3.8.3) \quad \forall g, h \in A^{\text{old}}: gh \in O^{\text{old}} \Leftrightarrow gh \in O^{\text{new}}.$$

$$(3.8.4) \quad \forall g \in A^{\text{old}}: g \in S^{\text{old}} \Leftrightarrow g \in S^{\text{new}}.$$

The following example demonstrates that the Schulze method, as defined in section 2.2, does not satisfy IPDA. This example has been proposed by Eppley (2003).

3.8.1. Situation #1

Example 8 (old):

3 voters $a \succ_v b \succ_v d \succ_v c$
 5 voters $a \succ_v d \succ_v b \succ_v c$
 1 voter $a \succ_v d \succ_v c \succ_v b$
 2 voters $b \succ_v a \succ_v d \succ_v c$
 2 voters $b \succ_v d \succ_v c \succ_v a$
 4 voters $c \succ_v a \succ_v b \succ_v d$
 6 voters $c \succ_v b \succ_v a \succ_v d$
 2 voters $d \succ_v b \succ_v c \succ_v a$
 5 voters $d \succ_v c \succ_v a \succ_v b$

The pairwise matrix N^{old} looks as follows:

	$N^{\text{old}}[*,a]$	$N^{\text{old}}[*,b]$	$N^{\text{old}}[*,c]$	$N^{\text{old}}[*,d]$
$N^{\text{old}}[a,*]$	---	18	11	21
$N^{\text{old}}[b,*]$	12	---	14	17
$N^{\text{old}}[c,*]$	19	16	---	10
$N^{\text{old}}[d,*]$	9	13	20	---

The corresponding digraph looks as follows:

The following table lists the strongest paths, as determined by the Floyd-Warshall algorithm, as defined in section 2.3.1. The critical links of the strongest paths are underlined:

	... to <i>a</i>	... to <i>b</i>	... to <i>c</i>	... to <i>d</i>	... to every other alternative
from <i>a</i> ...	---	 <i>a</i> , <u>(18,12)</u> , <i>b</i>	 <i>a</i> , (21,9), <i>d</i> , <u>(20,10)</u> , <i>c</i>	 <i>a</i> , <u>(21,9)</u> , <i>d</i>	
from <i>b</i> ...	 <i>b</i> , (17,13), <i>d</i> , (20,10), <i>c</i> , (19,11), <i>a</i>	---	 <i>b</i> , (17,13), <i>d</i> , (20,10), <i>c</i>	 <i>b</i> , <u>(17,13)</u> , <i>d</i>	
from <i>c</i> ...	 <i>c</i> , <u>(19,11)</u> , <i>a</i>	 <i>c</i> , (19,11), <i>a</i> , <u>(18,12)</u> , <i>b</i>	---	 <i>c</i> , (19,11), <i>a</i> , (21,9), <i>d</i>	
from <i>d</i> ...	 <i>d</i> , (20,10), <i>c</i> , <u>(19,11)</u> , <i>a</i>	 <i>d</i> , (20,10), <i>c</i> , (19,11), <i>a</i> , <u>(18,12)</u> , <i>b</i>	 <i>d</i> , <u>(20,10)</u> , <i>c</i>	---	
from every other alternative ...					---

The strengths of the strongest paths are:

	$P_D[*,a]$	$P_D[*,b]$	$P_D[*,c]$	$P_D[*,d]$
$P_D[a,*]$	---	(18,12)	(20,10)	(21,9)
$P_D[b,*]$	(17,13)	---	(17,13)	(17,13)
$P_D[c,*]$	(19,11)	(18,12)	---	(19,11)
$P_D[d,*]$	(19,11)	(18,12)	(20,10)	---

We get $O^{\text{old}} = \{ab, ac, ad, cb, db, dc\}$ and $S^{\text{old}} = \{a\}$.

Suppose, the strongest paths are calculated with the Floyd-Warshall algorithm, as defined in section 2.3.1. Then the following table documents the $C \cdot (C-1) \cdot (C-2) = 24$ steps of the Floyd-Warshall algorithm.

We start with

- $P_D[i,j] := (N^{\text{old}}[i,j], N^{\text{old}}[j,i])$ for all $i \in A$ and $j \in A \setminus \{i\}$.
- $\text{pred}[i,j] := i$ for all $i \in A$ and $j \in A \setminus \{i\}$.

	i	j	k	$P_D[j,k]$	$P_D[j,i]$	$P_D[i,k]$	$pred[j,k]$	$pred[i,k]$	result
1	a	b	c	(14,16)	(12,18)	(11,19)	b	a	
2	a	b	d	(17,13)	(12,18)	(21,9)	b	a	
3	a	c	b	(16,14)	(19,11)	(18,12)	c	a	$P_D[c,b]$ is updated from (16,14) to (18,12); $pred[c,b]$ is updated from c to a .
4	a	c	d	(10,20)	(19,11)	(21,9)	c	a	$P_D[c,d]$ is updated from (10,20) to (19,11); $pred[c,d]$ is updated from c to a .
5	a	d	b	(13,17)	(9,21)	(18,12)	d	a	
6	a	d	c	(20,10)	(9,21)	(11,19)	d	a	
7	b	a	c	(11,19)	(18,12)	(14,16)	a	b	$P_D[a,c]$ is updated from (11,19) to (14,16); $pred[a,c]$ is updated from a to b .
8	b	a	d	(21,9)	(18,12)	(17,13)	a	b	
9	b	c	a	(19,11)	(18,12)	(12,18)	c	b	
10	b	c	d	(19,11)	(18,12)	(17,13)	a	b	
11	b	d	a	(9,21)	(13,17)	(12,18)	d	b	$P_D[d,a]$ is updated from (9,21) to (12,18); $pred[d,a]$ is updated from d to b .
12	b	d	c	(20,10)	(13,17)	(14,16)	d	b	
13	c	a	b	(18,12)	(14,16)	(18,12)	a	a	
14	c	a	d	(21,9)	(14,16)	(19,11)	a	a	
15	c	b	a	(12,18)	(14,16)	(19,11)	b	c	$P_D[b,a]$ is updated from (12,18) to (14,16); $pred[b,a]$ is updated from b to c .
16	c	b	d	(17,13)	(14,16)	(19,11)	b	a	
17	c	d	a	(12,18)	(20,10)	(19,11)	b	c	$P_D[d,a]$ is updated from (12,18) to (19,11); $pred[d,a]$ is updated from b to c .
18	c	d	b	(13,17)	(20,10)	(18,12)	d	a	$P_D[d,b]$ is updated from (13,17) to (18,12); $pred[d,b]$ is updated from d to a .
19	d	a	b	(18,12)	(21,9)	(18,12)	a	a	
20	d	a	c	(14,16)	(21,9)	(20,10)	b	d	$P_D[a,c]$ is updated from (14,16) to (20,10); $pred[a,c]$ is updated from b to d .
21	d	b	a	(14,16)	(17,13)	(19,11)	c	c	$P_D[b,a]$ is updated from (14,16) to (17,13).
22	d	b	c	(14,16)	(17,13)	(20,10)	b	d	$P_D[b,c]$ is updated from (14,16) to (17,13); $pred[b,c]$ is updated from b to d .
23	d	c	a	(19,11)	(19,11)	(19,11)	c	c	
24	d	c	b	(18,12)	(19,11)	(18,12)	a	a	

3.8.2. Situation #2

Suppose alternative e is added as follows:

Example 8 (new):

3 voters	$a \succ_v b \succ_v d \succ_v e \succ_v c$
5 voters	$a \succ_v d \succ_v e \succ_v b \succ_v c$
1 voter	$a \succ_v d \succ_v e \succ_v c \succ_v b$
2 voters	$b \succ_v a \succ_v d \succ_v e \succ_v c$
2 voters	$b \succ_v d \succ_v e \succ_v c \succ_v a$
4 voters	$c \succ_v a \succ_v b \succ_v d \succ_v e$
6 voters	$c \succ_v b \succ_v a \succ_v d \succ_v e$
2 voters	$d \succ_v b \succ_v e \succ_v c \succ_v a$
5 voters	$d \succ_v e \succ_v c \succ_v a \succ_v b$

The newly added alternative e is Pareto-dominated by alternative d , because $d \succ_v e$ for every voter $v \in V$. Therefore, (3.8.1) – (3.8.4) say that the result should not change.

The pairwise matrix N^{new} looks as follows:

	$N^{\text{new}}[*,a]$	$N^{\text{new}}[*,b]$	$N^{\text{new}}[*,c]$	$N^{\text{new}}[*,d]$	$N^{\text{new}}[*,e]$
$N^{\text{new}}[a,*]$	---	18	11	21	21
$N^{\text{new}}[b,*]$	12	---	14	17	19
$N^{\text{new}}[c,*]$	19	16	---	10	10
$N^{\text{new}}[d,*]$	9	13	20	---	30
$N^{\text{new}}[e,*]$	9	11	20	0	---

The corresponding digraph looks as follows:

The following table lists the strongest paths, as determined by the Floyd-Warshall algorithm, as defined in section 2.3.1. The critical links of the strongest paths are underlined:

	... to <i>a</i>	... to <i>b</i>	... to <i>c</i>	... to <i>d</i>	... to <i>e</i>
from <i>a</i> ...	---	<i>a</i> , <u>(18,12)</u> , <i>b</i>	<i>a</i> , (21,9), <i>d</i> , <u>(20,10)</u> , <i>c</i>	<i>a</i> , <u>(21,9)</u> , <i>d</i>	<i>a</i> , <u>(21,9)</u> , <i>e</i>
from <i>b</i> ...	<i>b</i> , <u>(19,11)</u> , <i>e</i> , (20,10), <i>c</i> , <u>(19,11)</u> , <i>a</i>	---	<i>b</i> , <u>(19,11)</u> , <i>e</i> , (20,10), <i>c</i>	<i>b</i> , <u>(19,11)</u> , <i>e</i> , (20,10), <i>c</i> , <u>(19,11)</u> , <i>a</i> , (21,9), <i>d</i>	<i>b</i> , <u>(19,11)</u> , <i>e</i>
from <i>c</i> ...	<i>c</i> , <u>(19,11)</u> , <i>a</i>	<i>c</i> , (19,11), <i>a</i> , <u>(18,12)</u> , <i>b</i>	---	<i>c</i> , <u>(19,11)</u> , <i>a</i> , (21,9), <i>d</i>	<i>c</i> , <u>(19,11)</u> , <i>a</i> , (21,9), <i>e</i>
from <i>d</i> ...	<i>d</i> , (20,10), <i>c</i> , <u>(19,11)</u> , <i>a</i>	<i>d</i> , (20,10), <i>c</i> , (19,11), <i>a</i> , <u>(18,12)</u> , <i>b</i>	<i>d</i> , <u>(20,10)</u> , <i>c</i>	---	<i>d</i> , <u>(30,0)</u> , <i>e</i>
from <i>e</i> ...	<i>e</i> , (20,10), <i>c</i> , <u>(19,11)</u> , <i>a</i>	<i>e</i> , (20,10), <i>c</i> , (19,11), <i>a</i> , <u>(18,12)</u> , <i>b</i>	<i>e</i> , <u>(20,10)</u> , <i>c</i>	<i>e</i> , (20,10), <i>c</i> , <u>(19,11)</u> , <i>a</i> , (21,9), <i>d</i>	---

The strongest path from a to b is:
 $a, (18,12), b$

The strongest path from a to c is:
 $a, (21,9), d, (20,10), c$

The strongest path from a to d is:
 $a, (21,9), d$

The strongest path from a to e is:
 $a, (21,9), e$

These are the strongest paths
 from a to every other alternative.

The strongest path from b to a is:
 b , $(19,11)$, e , $(20,10)$, c , $(19,11)$, a

The strongest path from b to c is:
 b , $(19,11)$, e , $(20,10)$, c

The strongest path from b to d is:
 b , $(19,11)$, e , $(20,10)$, c ,
 $(19,11)$, a , $(21,9)$, d

The strongest path from b to e is:
 b , $(19,11)$, e

These are the strongest paths
 from b to every other alternative.

The strongest path from c to a is:
 $c, \underline{(19,11)}, a$

The strongest path from c to b is:
 $c, \underline{(19,11)}, a, \underline{(18,12)}, b$

The strongest path from c to d is:
 $c, \underline{(19,11)}, a, \underline{(21,9)}, d$

The strongest path from c to e is:
 $c, \underline{(19,11)}, a, \underline{(21,9)}, e$

These are the strongest paths
 from c to every other alternative.

The strongest path from d to a is:
 $d, (20,10), c, (19,11), a$

The strongest path from d to b is:
 $d, (20,10), c, (19,11), a, (18,12), b$

The strongest path from d to c is:
 $d, (20,10), c$

The strongest path from d to e is:
 $d, (30,0), e$

These are the strongest paths
 from d to every other alternative.

The strongest path from e to a is:
 e , $(20,10)$, c , $(19,11)$, a

The strongest path from e to b is:
 e , $(20,10)$, c , $(19,11)$, a , $(18,12)$, b

The strongest path from e to c is:
 e , $(20,10)$, c

The strongest path from e to d is:
 e , $(20,10)$, c , $(19,11)$, a , $(21,9)$, d

These are the strongest paths
 from e to every other alternative.

These are the strongest paths from every other alternative to a .

These are the strongest paths from every other alternative to b .

These are the strongest paths from every other alternative to c .

These are the strongest paths from every other alternative to d .

These are the strongest paths from every other alternative to e .

Therefore, the strengths of the strongest paths are:

	$P_D[*,a]$	$P_D[*,b]$	$P_D[*,c]$	$P_D[*,d]$	$P_D[*,e]$
$P_D[a,*]$	---	(18,12)	(20,10)	(21,9)	(21,9)
$P_D[b,*]$	(19,11)	---	(19,11)	(19,11)	(19,11)
$P_D[c,*]$	(19,11)	(18,12)	---	(19,11)	(19,11)
$P_D[d,*]$	(19,11)	(18,12)	(20,10)	---	(30,0)
$P_D[e,*]$	(19,11)	(18,12)	(20,10)	(19,11)	---

We get $\mathcal{O}^{\text{new}} = \{ac, ad, ae, ba, bc, bd, be, dc, de, ec\}$ and $\mathcal{S}^{\text{new}} = \{b\}$.

Example 8 shows that the Schulze method, as defined in section 2.2, violates IPDA, as defined in (3.8.1) – (3.8.4). For example, we have (1) $ab \in \mathcal{O}^{\text{old}}$ and $ba \in \mathcal{O}^{\text{new}}$, (2) $cb \in \mathcal{O}^{\text{old}}$ and $bc \in \mathcal{O}^{\text{new}}$, (3) $db \in \mathcal{O}^{\text{old}}$ and $bd \in \mathcal{O}^{\text{new}}$, (4) $a \in \mathcal{S}^{\text{old}}$ and $a \notin \mathcal{S}^{\text{new}}$, and (5) $b \notin \mathcal{S}^{\text{old}}$ and $b \in \mathcal{S}^{\text{new}}$.

Suppose, the strongest paths are calculated with the Floyd-Warshall algorithm, as defined in section 2.3.1. Then the following table documents the $C \cdot (C-1) \cdot (C-2) = 60$ steps of the Floyd-Warshall algorithm.

We start with

- $P_D[i,j] := (N^{\text{new}}[i,j], N^{\text{new}}[j,i])$ for all $i \in A$ and $j \in A \setminus \{i\}$.
- $\text{pred}[i,j] := i$ for all $i \in A$ and $j \in A \setminus \{i\}$.

	i	j	k	$P_D[j,k]$	$P_D[j,i]$	$P_D[i,k]$	$pred[j,k]$	$pred[i,k]$	result
1	a	b	c	(14,16)	(12,18)	(11,19)	b	a	
2	a	b	d	(17,13)	(12,18)	(21,9)	b	a	
3	a	b	e	(19,11)	(12,18)	(21,9)	b	a	
4	a	c	b	(16,14)	(19,11)	(18,12)	c	a	$P_D[c,b]$ is updated from (16,14) to (18,12); $pred[c,b]$ is updated from c to a .
5	a	c	d	(10,20)	(19,11)	(21,9)	c	a	$P_D[c,d]$ is updated from (10,20) to (19,11); $pred[c,d]$ is updated from c to a .
6	a	c	e	(10,20)	(19,11)	(21,9)	c	a	$P_D[c,e]$ is updated from (10,20) to (19,11); $pred[c,e]$ is updated from c to a .

57	e	c	d	(19,11)	(19,11)	(19,11)	a	a	
58	e	d	a	(19,11)	(30,0)	(19,11)	c	c	
59	e	d	b	(18,12)	(30,0)	(18,12)	a	a	
60	e	d	c	(20,10)	(30,0)	(20,10)	d	e	

3.9. Example 9

3.9.1. Situation #1

Example 9 (old):

5 voters $a \succ_v c \succ_v d \succ_v b$
2 voters $b \succ_v c \succ_v d \succ_v a$
4 voters $b \succ_v d \succ_v a \succ_v c$
2 voters $c \succ_v d \succ_v a \succ_v b$

The pairwise matrix N^{old} looks as follows:

	$N^{\text{old}}[*,a]$	$N^{\text{old}}[*,b]$	$N^{\text{old}}[*,c]$	$N^{\text{old}}[*,d]$
$N^{\text{old}}[a,*]$	---	7	9	5
$N^{\text{old}}[b,*]$	6	---	6	6
$N^{\text{old}}[c,*]$	4	7	---	9
$N^{\text{old}}[d,*]$	8	7	4	---

The corresponding digraph looks as follows:

The following table lists the strongest paths, as determined by the Floyd-Warshall algorithm, as defined in section 2.3.1. The critical links of the strongest paths are underlined:

	... to <i>a</i>	... to <i>b</i>	... to <i>c</i>	... to <i>d</i>	... to every other alternative
from <i>a</i> ...	---	 <i>a</i> , <u>(7,6)</u> , <i>b</i>	 <i>a</i> , <u>(9,4)</u> , <i>c</i>	 <i>a</i> , <u>(9,4)</u> , <i>c</i> , <u>(9,4)</u> , <i>d</i>	
from <i>b</i> ...	 <i>b</i> , <u>(6,7)</u> , <i>a</i>	---	 <i>b</i> , <u>(6,7)</u> , <i>c</i>	 <i>b</i> , <u>(6,7)</u> , <i>d</i>	
from <i>c</i> ...	 <i>c</i> , <u>(9,4)</u> , <i>d</i> , <u>(8,5)</u> , <i>a</i>	 <i>c</i> , <u>(7,6)</u> , <i>b</i>	---	 <i>c</i> , <u>(9,4)</u> , <i>d</i>	
from <i>d</i> ...	 <i>d</i> , <u>(8,5)</u> , <i>a</i>	 <i>d</i> , <u>(7,6)</u> , <i>b</i>	 <i>d</i> , <u>(8,5)</u> , <i>a</i> , <u>(9,4)</u> , <i>c</i>	---	
from every other alternative ...					---

The strengths of the strongest paths are:

	$P_D[*,a]$	$P_D[*,b]$	$P_D[*,c]$	$P_D[*,d]$
$P_D[a,*]$	---	(7,6)	(9,4)	(9,4)
$P_D[b,*]$	(6,7)	---	(6,7)	(6,7)
$P_D[c,*]$	(8,5)	(7,6)	---	(9,4)
$P_D[d,*]$	(8,5)	(7,6)	(8,5)	---

We get $O^{\text{old}} = \{ab, ac, ad, cb, cd, db\}$ and $S^{\text{old}} = \{a\}$.

As there are no paths from alternative b to the other alternatives that contain only wins or ties, these paths must necessarily contain losses. These losses are marked in green in the above table of the strongest paths.

Suppose, the strongest paths are calculated with the Floyd-Warshall algorithm, as defined in section 2.3.1. Then the following table documents the $C \cdot (C-1) \cdot (C-2) = 24$ steps of the Floyd-Warshall algorithm.

We start with

- $P_D[i,j] := (N^{\text{old}}[i,j], N^{\text{old}}[j,i])$ for all $i \in A$ and $j \in A \setminus \{i\}$.
- $\text{pred}[i,j] := i$ for all $i \in A$ and $j \in A \setminus \{i\}$.

	i	j	k	$P_D[j,k]$	$P_D[j,i]$	$P_D[i,k]$	$pred[j,k]$	$pred[i,k]$	result
1	a	b	c	(6,7)	(6,7)	(9,4)	b	a	
2	a	b	d	(6,7)	(6,7)	(5,8)	b	a

23	d	c	a	(6,7)	(9,4)	(8,5)	b	d	$P_D[c,a]$ is updated from (6,7) to (8,5); $pred[c,a]$ is updated from b to d .
24	d	c	b	(7,6)	(9,4)	(7,6)	c	d	

3.9.2. Situation #2

Suppose alternative e is added as follows:

Example 9 (new):

5 voters $a \succ_v e \succ_v c \succ_v d \succ_v b$
 2 voters $b \succ_v c \succ_v d \succ_v a \succ_v e$
 4 voters $b \succ_v d \succ_v a \succ_v e \succ_v c$
 2 voters $c \succ_v d \succ_v a \succ_v b \succ_v e$

The newly added alternative e is Pareto-dominated by alternative a , because $a \succ_v e$ for every voter $v \in V$. Therefore, (3.8.1) – (3.8.4) say that the result should not change.

The pairwise matrix N^{new} looks as follows:

	$N^{\text{new}}[*,a]$	$N^{\text{new}}[*,b]$	$N^{\text{new}}[*,c]$	$N^{\text{new}}[*,d]$	$N^{\text{new}}[*,e]$
$N^{\text{new}}[a,*]$	---	7	9	5	13
$N^{\text{new}}[b,*]$	6	---	6	6	8
$N^{\text{new}}[c,*]$	4	7	---	9	4
$N^{\text{new}}[d,*]$	8	7	4	---	8
$N^{\text{new}}[e,*]$	0	5	9	5	---

The corresponding digraph looks as follows:

The following table lists the strongest paths, as determined by the Floyd-Warshall algorithm, as defined in section 2.3.1. The critical links of the strongest paths are underlined:

	... to <i>a</i>	... to <i>b</i>	... to <i>c</i>	... to <i>d</i>	... to <i>e</i>
from <i>a</i> ...	---	<i>a</i> , <u>(7,6)</u> , <i>b</i>	<i>a</i> , <u>(9,4)</u> , <i>c</i>	<i>a</i> , <u>(9,4)</u> , <i>c</i> , <u>(9,4)</u> , <i>d</i>	<i>a</i> , <u>(13,0)</u> , <i>e</i>
from <i>b</i> ...	<i>b</i> , <u>(8,5)</u> , <i>e</i> , (9,4), <i>c</i> , (9,4), <i>d</i> , <u>(8,5)</u> , <i>a</i>	---	<i>b</i> , <u>(8,5)</u> , <i>e</i> , (9,4), <i>c</i>	<i>b</i> , <u>(8,5)</u> , <i>e</i> , (9,4), <i>c</i> , (9,4), <i>d</i>	<i>b</i> , <u>(8,5)</u> , <i>e</i>
from <i>c</i> ...	<i>c</i> , (9,4), <i>d</i> , <u>(8,5)</u> , <i>a</i>	<i>c</i> , <u>(7,6)</u> , <i>b</i>	---	<i>c</i> , <u>(9,4)</u> , <i>d</i>	<i>c</i> , (9,4), <i>d</i> , <u>(8,5)</u> , <i>e</i>
from <i>d</i> ...	<i>d</i> , <u>(8,5)</u> , <i>a</i>	<i>d</i> , <u>(7,6)</u> , <i>b</i>	<i>d</i> , <u>(8,5)</u> , <i>a</i> , (9,4), <i>c</i>	---	<i>d</i> , <u>(8,5)</u> , <i>e</i>
from <i>e</i> ...	<i>e</i> , (9,4), <i>c</i> , (9,4), <i>d</i> , <u>(8,5)</u> , <i>a</i>	<i>e</i> , (9,4), <i>c</i> , <u>(7,6)</u> , <i>b</i>	<i>e</i> , <u>(9,4)</u> , <i>c</i>	<i>e</i> , <u>(9,4)</u> , <i>c</i> , <u>(9,4)</u> , <i>d</i>	---

The strongest path from a to b is:
 $a, \underline{(7,6)}, b$

The strongest path from a to c is:
 $a, \underline{(9,4)}, c$

The strongest path from a to d is:
 $a, \underline{(9,4)}, c, \underline{(9,4)}, d$

The strongest path from a to e is:
 $a, \underline{(13,0)}, e$

These are the strongest paths
from a to every other alternative.

The strongest path from b to a is:
 $b, \underline{(8,5)}, e, (9,4), c, (9,4), d, \underline{(8,5)}, a$

The strongest path from b to c is:
 $b, \underline{(8,5)}, e, (9,4), c$

The strongest path from b to d is:
 $b, \underline{(8,5)}, e, (9,4), c, (9,4), d$

The strongest path from b to e is:
 $b, \underline{(8,5)}, e$

These are the strongest paths
 from b to every other alternative.

The strongest path from c to a is:
 c , $(9,4)$, d , $(8,5)$, a

The strongest path from c to b is:
 c , $(7,6)$, b

The strongest path from c to d is:
 c , $(9,4)$, d

The strongest path from c to e is:
 c , $(9,4)$, d , $(8,5)$, e

These are the strongest paths
 from c to every other alternative.

The strongest path from d to a is:
 $d, \underline{(8,5)}, a$

The strongest path from d to b is:
 $d, \underline{(7,6)}, b$

The strongest path from d to c is:
 $d, \underline{(8,5)}, a, (9,4), c$

The strongest path from d to e is:
 $d, \underline{(8,5)}, e$

These are the strongest paths
 from d to every other alternative.

The strongest path from e to a is:
 e , $(9,4)$, c , $(9,4)$, d , $(8,5)$, a

The strongest path from e to b is:
 e , $(9,4)$, c , $(7,6)$, b

The strongest path from e to c is:
 e , $(9,4)$, c

The strongest path from e to d is:
 e , $(9,4)$, c , $(9,4)$, d

These are the strongest paths
 from e to every other alternative.

These are the strongest paths from every other alternative to a .

These are the strongest paths from every other alternative to b .

These are the strongest paths from every other alternative to c .

These are the strongest paths from every other alternative to d .

These are the strongest paths from every other alternative to e .

Therefore, the strengths of the strongest paths are:

	$P_D[*,a]$	$P_D[*,b]$	$P_D[*,c]$	$P_D[*,d]$	$P_D[*,e]$
$P_D[a,*]$	---	(7,6)	(9,4)	(9,4)	(13,0)
$P_D[b,*]$	(8,5)	---	(8,5)	(8,5)	(8,5)
$P_D[c,*]$	(8,5)	(7,6)	---	(9,4)	(8,5)
$P_D[d,*]$	(8,5)	(7,6)	(8,5)	---	(8,5)
$P_D[e,*]$	(8,5)	(7,6)	(9,4)	(9,4)	---

We get $\mathcal{O}^{\text{new}} = \{ac, ad, ae, ba, bc, bd, be, cd, ec, ed\}$ and $\mathcal{S}^{\text{new}} = \{b\}$.

Example 9 shows that the Schulze method, as defined in section 2.2, violates IPDA, as defined in (3.8.1) – (3.8.4). For example, we have (1) $ab \in \mathcal{O}^{\text{old}}$ and $ba \in \mathcal{O}^{\text{new}}$, (2) $cb \in \mathcal{O}^{\text{old}}$ and $bc \in \mathcal{O}^{\text{new}}$, (3) $db \in \mathcal{O}^{\text{old}}$ and $bd \in \mathcal{O}^{\text{new}}$, (4) $a \in \mathcal{S}^{\text{old}}$ and $a \notin \mathcal{S}^{\text{new}}$, and (5) $b \notin \mathcal{S}^{\text{old}}$ and $b \in \mathcal{S}^{\text{new}}$.

Suppose, the strongest paths are calculated with the Floyd-Warshall algorithm, as defined in section 2.3.1. Then the following table documents the $C \cdot (C-1) \cdot (C-2) = 60$ steps of the Floyd-Warshall algorithm.

We start with

- $P_D[i,j] := (N^{\text{new}}[i,j], N^{\text{new}}[j,i])$ for all $i \in A$ and $j \in A \setminus \{i\}$.
- $\text{pred}[i,j] := i$ for all $i \in A$ and $j \in A \setminus \{i\}$.

	i	j	k	$P_D[j,k]$	$P_D[j,i]$	$P_D[i,k]$	$pred[j,k]$	$pred[i,k]$	result
1	a	b	c	(6,7)	(6,7)	(9,4)	b	a	
2	a	b	d	(6,7)	(6,7)	(5,8)	b	a	
3	a	b	e	(8,5)	(6,7)	(13,0)	b	a	
4	a	c	b	(7,6)	(4,9)	(7,6)	c	a	
5	a	c	d	(9,4)	(4,9)	(5,8)	c	a	
6	a	c	e	(4,9)	(4,9)	(13,0)	c	a	
7	a	d	b	(7,6)	(8,5)	(7,6)	d	a	
8	a	d	c	(4,9)	(8,5)	(9,4)	d	a	$P_D[d,c]$ is updated from (4,9) to (8,5); $pred[d,c]$ is updated from d to a .
9	a	d	e	(8,5)	(8,5)	(13,0)	d	a	
10	a	e	b	(5,8)	(0,13)	(7,6)	e	a	
11	a	e	c	(9,4)	(0,13)	(9,4)	e	a	
12	a	e	d	(5,8)	(0,13)	(5,8)	e	a	
13	b	a	c	(9,4)	(7,6)	(6,7)	a	b	
14	b	a	d	(5,8)	(7,6)	(6,7)	a	b	$P_D[a,d]$ is updated from (5,8) to (6,7); $pred[a,d]$ is updated from a to b .
15	b	a	e	(13,0)	(7,6)	(8,5)	a	b	
16	b	c	a	(4,9)	(7,6)	(6,7)	c	b	$P_D[c,a]$ is updated from (4,9) to (6,7); $pred[c,a]$ is updated from c to b .
17	b	c	d	(9,4)	(7,6)	(6,7)	c	b	
18	b	c	e	(4,9)	(7,6)	(8,5)	c	b	$P_D[c,e]$ is updated from (4,9) to (7,6); $pred[c,e]$ is updated from c to b .
19	b	d	a	(8,5)	(7,6)	(6,7)	d	b	
20	b	d	c	(8,5)	(7,6)	(6,7)	a	b	
21	b	d	e	(8,5)	(7,6)	(8,5)	d	b	
22	b	e	a	(0,13)	(5,8)	(6,7)	e	b	$P_D[e,a]$ is updated from (0,13) to (5,8); $pred[e,a]$ is updated from e to b .
23	b	e	c	(9,4)	(5,8)	(6,7)	e	b	
24	b	e	d	(5,8)	(5,8)	(6,7)	e	b	
25	c	a	b	(7,6)	(9,4)	(7,6)	a	c	
26	c	a	d	(6,7)	(9,4)	(9,4)	b	c	$P_D[a,d]$ is updated from (6,7) to (9,4); $pred[a,d]$ is updated from b to c .
27	c	a	e	(13,0)	(9,4)	(7,6)	a	b	
28	c	b	a	(6,7)	(6,7)	(6,7)	b	b	
29	c	b	d	(6,7)	(6,7)	(9,4)	b	c	
30	c	b	e	(8,5)	(6,7)	(7,6)	b	b	

	i	j	k	$P_D[j,k]$	$P_D[j,i]$	$P_D[i,k]$	$pred[j,k]$	$pred[i,k]$	result
31	c	d	a	(8,5)	(8,5)	(6,7)	d	b	
32	c	d	b	(7,6)	(8,5)	(7,6)	d	c	
33	c	d	e	(8,5)	(8,5)	(7,6)	d	b	
34	c	e	a	(5,8)	(9,4)	(6,7)	b	b	$P_D[e,a]$ is updated from (5,8) to (6,7).
35	c	e	b	(5,8)	(9,4)	(7,6)	e	c	$P_D[e,b]$ is updated from (5,8) to (7,6); $pred[e,b]$ is updated from e to c .
36	c	e	d	(5,8)	(9,4)	(9,4)	e	c	$P_D[e,d]$ is updated from (5,8) to (9,4); $pred[e,d]$ is updated from e to c .
37	d	a	b	(7,6)	(9,4)	(7,6)	a	d	
38	d	a	c	(9,4)	(9,4)	(8,5)	a	a	
39	d	a	e	(13,0)	(9,4)	(8,5)	a	d	
40	d	b	a	(6,7)	(6,7)	(8,5)	b	d	
41	d	b	c	(6,7)	(6,7)	(8,5)	b	a	
42	d	b	e	(8,5)	(6,7)	(8,5)	b	d	
43	d	c	a	(6,7)	(9,4)	(8,5)	b	d	$P_D[c,a]$ is updated from (6,7) to (8,5); $pred[c,a]$ is updated from b to d .

59	e	d	b	(7,6)	(8,5)	(7,6)	d	c	
60	e	d	c	(8,5)	(8,5)	(9,4)	a	e	

3.10. Example 10

When each voter $v \in V$ casts a linear order $\succ_v$ on A , then all definitions for $\succ_D$, that satisfy presumption (2.1.1), are equivalent. However, when some voters cast non-linear orders, then there are many possible definitions for the strength of a link. The following example illustrates how the different definitions for the strength of a link can lead to different winners.

Example 10:

6 voters	$a \succ_v b \succ_v c \succ_v d$
8 voters	$a \approx_v b \succ_v c \approx_v d$
8 voters	$a \approx_v c \succ_v b \approx_v d$
18 voters	$a \approx_v c \succ_v d \succ_v b$
8 voters	$a \approx_v c \approx_v d \succ_v b$
40 voters	$b \succ_v a \approx_v c \approx_v d$
4 voters	$c \succ_v b \succ_v d \succ_v a$
9 voters	$c \succ_v d \succ_v a \succ_v b$
8 voters	$c \approx_v d \succ_v a \approx_v b$
14 voters	$d \succ_v a \succ_v b \succ_v c$
11 voters	$d \succ_v b \succ_v c \succ_v a$
4 voters	$d \succ_v c \succ_v a \succ_v b$

The pairwise matrix N looks as follows:

	$N[*,a]$	$N[*,b]$	$N[*,c]$	$N[*,d]$
$N[a,*]$	---	67	28	40
$N[b,*]$	55	---	79	58
$N[c,*]$	36	59	---	45
$N[d,*]$	50	72	29	---

The corresponding digraph looks as follows:

a) margin

We get: $(N[b,c], N[c,b]) \succ_{\text{margin}} (N[c,d], N[d,c]) \succ_{\text{margin}} (N[d,b], N[b,d])$
 $\succ_{\text{margin}} (N[a,b], N[b,a]) \succ_{\text{margin}} (N[d,a], N[a,d]) \succ_{\text{margin}} (N[c,a], N[a,c])$.

The pairwise victories are:

bc with a margin of $N[b,c] - N[c,b] = 20$
 cd with a margin of $N[c,d] - N[d,c] = 16$
 db with a margin of $N[d,b] - N[b,d] = 14$
 ab with a margin of $N[a,b] - N[b,a] = 12$
 da with a margin of $N[d,a] - N[a,d] = 10$
 ca with a margin of $N[c,a] - N[a,c] = 8$

The following table lists the strongest paths, as determined by the Floyd-Warshall algorithm, as defined in section 2.3.1. The critical links of the strongest paths are underlined:

	... to <i>a</i>	... to <i>b</i>	... to <i>c</i>	... to <i>d</i>	... to every other alternative
from <i>a</i> ...	---	 <i>a</i> , <u>(67,55)</u> , <i>b</i>	 <i>a</i> , <u>(67,55)</u> , <i>b</i> , <u>(79,59)</u> , <i>c</i>	 <i>a</i> , <u>(67,55)</u> , <i>b</i> , <u>(79,59)</u> , <i>c</i> , <u>(45,29)</u> , <i>d</i>	
from <i>b</i> ...	 <i>b</i> , <u>(79,59)</u> , <i>c</i> , <u>(45,29)</u> , <i>d</i> , <u>(50,40)</u> , <i>a</i>	---	 <i>b</i> , <u>(79,59)</u> , <i>c</i>	 <i>b</i> , <u>(79,59)</u> , <i>c</i> , <u>(45,29)</u> , <i>d</i>	
from <i>c</i> ...	 <i>c</i> , <u>(45,29)</u> , <i>d</i> , <u>(50,40)</u> , <i>a</i>	 <i>c</i> , <u>(45,29)</u> , <i>d</i> , <u>(72,58)</u> , <i>b</i>	---	 <i>c</i> , <u>(45,29)</u> , <i>d</i>	
from <i>d</i> ...	 <i>d</i> , <u>(50,40)</u> , <i>a</i>	 <i>d</i> , <u>(72,58)</u> , <i>b</i>	 <i>d</i> , <u>(72,58)</u> , <i>b</i> , <u>(79,59)</u> , <i>c</i>	---	
from every other alternative ...					---

The strengths of the strongest paths are:

	$P_{\text{margin}}[* , a]$	$P_{\text{margin}}[* , b]$	$P_{\text{margin}}[* , c]$	$P_{\text{margin}}[* , d]$
$P_{\text{margin}}[a, *]$	---	(67,55)	(67,55)	(67,55)
$P_{\text{margin}}[b, *]$	(50,40)	---	(79,59)	(45,29)
$P_{\text{margin}}[c, *]$	(50,40)	(72,58)	---	(45,29)
$P_{\text{margin}}[d, *]$	(50,40)	(72,58)	(72,58)	---

We get $O_{\text{margin}} = \{ab, ac, ad, bc, bd, cd\}$ and $S_{\text{margin}} = \{a\}$.

Suppose, the strongest paths are calculated with the Floyd-Warshall algorithm, as defined in section 2.3.1. Then the following table documents the $C \cdot (C-1) \cdot (C-2) = 24$ steps of the Floyd-Warshall algorithm.

We start with

- $P_{\text{margin}}[i, j] := (N[i, j], N[j, i])$ for all $i \in A$ and $j \in A \setminus \{i\}$.
- $\text{pred}[i, j] := i$ for all $i \in A$ and $j \in A \setminus \{i\}$.

	i	j	k	$P_{\text{margin}}[j,k]$	$P_{\text{margin}}[j,i]$	$P_{\text{margin}}[i,k]$	$\text{pred}[j,k]$	$\text{pred}[i,k]$	result
1	a	b	c	(79,59)	(55,67)	(28,36)	b	a

16	c	b	d	(55,67)	(79,59)	(45,29)	a	c	$P_{\text{margin}}[b,d]$ is updated from (55,67) to (45,29); $\text{pred}[b,d]$ is updated from a to c .
17	c	d	a	(50,40)	(72,58)	(36,28)	d	c	
18	c	d	b	(72,58)	(72,58)	(36,28)	d	a	
19	d	a	b	(67,55)	(67,55)	(72,58)	a	d	
20	d	a	c	(67,55)	(67,55)	(72,58)	b	b	
21	d	b	a	(36,28)	(45,29)	(50,40)	c	d	$P_{\text{margin}}[b,a]$ is updated from (36,28) to (50,40); $\text{pred}[b,a]$ is updated from c to d .
22	d	b	c	(79,59)	(45,29)	(72,58)	b	b	
23	d	c	a	(36,28)	(45,29)	(50,40)	c	d	$P_{\text{margin}}[c,a]$ is updated from (36,28) to (50,40); $\text{pred}[c,a]$ is updated from c to d .
24	d	c	b	(36,28)	(45,29)	(72,58)	a	d	$P_{\text{margin}}[c,b]$ is updated from (36,28) to (72,58); $\text{pred}[c,b]$ is updated from a to d .

b) ratio

We get: $(N[c,d],N[d,c]) \succ_{ratio} (N[b,c],N[c,b]) \succ_{ratio} (N[c,a],N[a,c]) \succ_{ratio}$
 $(N[d,a],N[a,d]) \succ_{ratio} (N[d,b],N[b,d]) \succ_{ratio} (N[a,b],N[b,a])$.

The pairwise victories are:

cd with a ratio of $N[c,d] / N[d,c] = 1.552$
 bc with a ratio of $N[b,c] / N[c,b] = 1.339$
 ca with a ratio of $N[c,a] / N[a,c] = 1.286$
 da with a ratio of $N[d,a] / N[a,d] = 1.250$
 db with a ratio of $N[d,b] / N[b,d] = 1.241$
 ab with a ratio of $N[a,b] / N[b,a] = 1.218$

The following table lists the strongest paths, as determined by the Floyd-Warshall algorithm, as defined in section 2.3.1. The critical links of the strongest paths are underlined:

	... to <i>a</i>	... to <i>b</i>	... to <i>c</i>	... to <i>d</i>	... to every other alternative
from <i>a</i> ...	---	 <i>a</i> , <u>(67,55)</u> , <i>b</i>	 <i>a</i> , <u>(67,55)</u> , <i>b</i> , <u>(79,59)</u> , <i>c</i>	 <i>a</i> , <u>(67,55)</u> , <i>b</i> , <u>(79,59)</u> , <i>c</i> , <u>(45,29)</u> , <i>d</i>	
from <i>b</i> ...	 <i>b</i> , <u>(79,59)</u> , <i>c</i> , <u>(36,28)</u> , <i>a</i>	---	 <i>b</i> , <u>(79,59)</u> , <i>c</i>	 <i>b</i> , <u>(79,59)</u> , <i>c</i> , <u>(45,29)</u> , <i>d</i>	
from <i>c</i> ...	 <i>c</i> , <u>(36,28)</u> , <i>a</i>	 <i>c</i> , <u>(45,29)</u> , <i>d</i> , <u>(72,58)</u> , <i>b</i>	---	 <i>c</i> , <u>(45,29)</u> , <i>d</i>	
from <i>d</i> ...	 <i>d</i> , <u>(50,40)</u> , <i>a</i>	 <i>d</i> , <u>(72,58)</u> , <i>b</i>	 <i>d</i> , <u>(72,58)</u> , <i>b</i> , <u>(79,59)</u> , <i>c</i>	---	
from every other alternative ...					---

The strengths of the strongest paths are:

	$P_{ratio}[* , a]$	$P_{ratio}[* , b]$	$P_{ratio}[* , c]$	$P_{ratio}[* , d]$
$P_{ratio}[a, *]$	---	(67,55)	(67,55)	(67,55)
$P_{ratio}[b, *]$	(36,28)	---	(79,59)	(79,59)
$P_{ratio}[c, *]$	(36,28)	(72,58)	---	(45,29)
$P_{ratio}[d, *]$	(50,40)	(72,58)	(72,58)	---

We get $O_{ratio} = \{ba, bc, bd, ca, cd, da\}$ and $S_{ratio} = \{b\}$.

Suppose, the strongest paths are calculated with the Floyd-Warshall algorithm, as defined in section 2.3.1. Then the following table documents the $C \cdot (C-1) \cdot (C-2) = 24$ steps of the Floyd-Warshall algorithm.

We start with

- $P_{ratio}[i, j] := (N[i, j], N[j, i])$ for all $i \in A$ and $j \in A \setminus \{i\}$.
- $pred[i, j] := i$ for all $i \in A$ and $j \in A \setminus \{i\}$.

	i	j	k	$P_{ratio}[j,k]$	$P_{ratio}[j,i]$	$P_{ratio}[i,k]$	$pred[j,k]$	$pred[i,k]$	result
1	a	b	c	(79,59)	(55,67)	(28,36)	b	a	
2	a	b	d	(58,72)	(55,67)	(40,50)	b	a	
3	a	c	b	(59,79)	(36,28)	(67,55)	c	a	$P_{ratio}[c,b]$ is updated from (59,79) to (67,55); $pred[c,b]$ is updated from c to a .
4	a	c	d	(45,29)	(36,28)	(40,50)	c	a	
5	a	d	b	(72,58)	(50,40)	(67,55)	d	a	
6	a	d	c	(29,45)	(50,40)	(28,36)	d	a	$P_{ratio}[d,c]$ is updated from (29,45) to (28,36); $pred[d,c]$ is updated from d to a .
7	b	a	c	(28,36)	(67,55)	(79,59)	a	b	$P_{ratio}[a,c]$ is updated from (28,36) to (67,55); $pred[a,c]$ is updated from a to b .
8	b	a	d	(40,50)	(67,55)	(58,72)	a	b	$P_{ratio}[a,d]$ is updated from (40,50) to (58,72); $pred[a,d]$ is updated from a to b .
9	b	c	a	(36,28)	(67,55)	(55,67)	c	b	
10	b	c	d	(45,29)	(67,55)	(58,72)	c	b	
11	b	d	a	(50,40)	(72,58)	(55,67)	d	b	
12	b	d	c	(28,36)	(72,58)	(79,59)	a	b	$P_{ratio}[d,c]$ is updated from (28,36) to (72,58); $pred[d,c]$ is updated from a to b .
13	c	a	b	(67,55)	(67,55)	(67,55)	a	a	
14	c	a	d	(58,72)	(67,55)	(45,29)	b	c	$P_{ratio}[a,d]$ is updated from (58,72) to (67,55); $pred[a,d]$ is updated from b to c .
15	c	b	a	(55,67)	(79,59)	(36,28)	b	c	$P_{ratio}[b,a]$ is updated from (55,67) to (36,28); $pred[b,a]$ is updated from b to c .
16	c	b	d	(58,72)	(79,59)	(45,29)	b	c	$P_{ratio}[b,d]$ is updated from (58,72) to (79,59); $pred[b,d]$ is updated from b to c .
17	c	d	a	(50,40)	(72,58)	(36,28)	d	c	
18	c	d	b	(72,58)	(72,58)	(67,55)	d	a	
19	d	a	b	(67,55)	(67,55)	(72,58)	a	d	
20	d	a	c	(67,55)	(67,55)	(72,58)	b	b	
21	d	b	a	(36,28)	(79,59)	(50,40)	c	d	
22	d	b	c	(79,59)	(79,59)	(72,58)	b	b	
23	d	c	a	(36,28)	(45,29)	(50,40)	c	d	
24	d	c	b	(67,55)	(45,29)	(72,58)	a	d	$P_{ratio}[c,b]$ is updated from (67,55) to (72,58); $pred[c,b]$ is updated from a to d .

c) winning votes

We get: $(N[b,c], N[c,b]) \succ_{win} (N[d,b], N[b,d]) \succ_{win} (N[a,b], N[b,a]) \succ_{win} (N[d,a], N[a,d]) \succ_{win} (N[c,d], N[d,c]) \succ_{win} (N[c,a], N[a,c])$.

The pairwise victories are:

bc with a support of $N[b,c] = 79$
 db with a support of $N[d,b] = 72$
 ab with a support of $N[a,b] = 67$
 da with a support of $N[d,a] = 50$
 cd with a support of $N[c,d] = 45$
 ca with a support of $N[c,a] = 36$

The following table lists the strongest paths, as determined by the Floyd-Warshall algorithm, as defined in section 2.3.1. The critical links of the strongest paths are underlined:

	... to <i>a</i>	... to <i>b</i>	... to <i>c</i>	... to <i>d</i>	... to every other alternative
from <i>a</i> ...	---	 <i>a</i> , <u>(67,55)</u> , <i>b</i>	 <i>a</i> , <u>(67,55)</u> , <i>b</i> , <u>(79,59)</u> , <i>c</i>	 <i>a</i> , <u>(67,55)</u> , <i>b</i> , <u>(79,59)</u> , <i>c</i> , <u>(45,29)</u> , <i>d</i>	
from <i>b</i> ...	 <i>b</i> , <u>(79,59)</u> , <i>c</i> , <u>(45,29)</u> , <i>d</i> , <u>(50,40)</u> , <i>a</i>	---	 <i>b</i> , <u>(79,59)</u> , <i>c</i>	 <i>b</i> , <u>(79,59)</u> , <i>c</i> , <u>(45,29)</u> , <i>d</i>	
from <i>c</i> ...	 <i>c</i> , <u>(45,29)</u> , <i>d</i> , <u>(50,40)</u> , <i>a</i>	 <i>c</i> , <u>(45,29)</u> , <i>d</i> , <u>(72,58)</u> , <i>b</i>	---	 <i>c</i> , <u>(45,29)</u> , <i>d</i>	
from <i>d</i> ...	 <i>d</i> , <u>(50,40)</u> , <i>a</i>	 <i>d</i> , <u>(72,58)</u> , <i>b</i>	 <i>d</i> , <u>(72,58)</u> , <i>b</i> , <u>(79,59)</u> , <i>c</i>	---	
from every other alternative ...					---

The strengths of the strongest paths are:

	$P_{win}[* ,a]$	$P_{win}[* ,b]$	$P_{win}[* ,c]$	$P_{win}[* ,d]$
$P_{win}[a,*]$	---	(67,55)	(67,55)	(45,29)
$P_{win}[b,*]$	(45,29)	---	(79,59)	(45,29)
$P_{win}[c,*]$	(45,29)	(45,29)	---	(45,29)
$P_{win}[d,*]$	(50,40)	(72,58)	(72,58)	---

We get $O_{win} = \{ab, ac, bc, da, db, dc\}$ and $S_{win} = \{d\}$.

Suppose, the strongest paths are calculated with the Floyd-Warshall algorithm, as defined in section 2.3.1. Then the following table documents the $C \cdot (C-1) \cdot (C-2) = 24$ steps of the Floyd-Warshall algorithm.

We start with

- $P_{win}[i,j] := (N[i,j], N[j,i])$ for all $i \in A$ and $j \in A \setminus \{i\}$.
- $pred[i,j] := i$ for all $i \in A$ and $j \in A \setminus \{i\}$.

	i	j	k	$P_{win}[j,k]$	$P_{win}[j,i]$	$P_{win}[i,k]$	$pred[j,k]$	$pred[i,k]$	result
1	a	b	c	(79,59)	(55,67)	(28,36)	b	a	
2	a	b	d	(58,72)	(55,67)	(40,50)	b	a	$P_{win}[b,d]$ is updated from (58,72) to (55,67); $pred[b,d]$ is updated from b to a .
3	a	c	b	(59,79)	(36,28)	(67,55)	c	a	$P_{win}[c,b]$ is updated from (59,79) to (36,28); $pred[c,b]$ is updated from c to a .

23	d	c	a	(36,28)	(45,29)	(50,40)	c	d	$P_{win}[c,a]$ is updated from (36,28) to (45,29); $pred[c,a]$ is updated from c to d .
24	d	c	b	(36,28)	(45,29)	(72,58)	a	d	$P_{win}[c,b]$ is updated from (36,28) to (45,29); $pred[c,b]$ is updated from a to d .

d) losing votes

We get: $(N[c,a],N[a,c]) \succ_{los} (N[c,d],N[d,c]) \succ_{los} (N[d,a],N[a,d]) \succ_{los}$
 $(N[a,b],N[b,a]) \succ_{los} (N[d,b],N[b,d]) \succ_{los} (N[b,c],N[c,b])$.

The pairwise victories are:

ca with an opposition of $N[a,c] = 28$
 cd with an opposition of $N[d,c] = 29$
 da with an opposition of $N[a,d] = 40$
 ab with an opposition of $N[b,a] = 55$
 db with an opposition of $N[b,d] = 58$
 bc with an opposition of $N[c,b] = 59$

The following table lists the strongest paths, as determined by the Floyd-Warshall algorithm, as defined in section 2.3.1. The critical links of the strongest paths are underlined:

	... to <i>a</i>	... to <i>b</i>	... to <i>c</i>	... to <i>d</i>	... to every other alternative
from <i>a</i> ...	---	 <i>a</i> , <u>(67,55)</u> , <i>b</i>	 <i>a</i> , (67,55), <i>b</i> , <u>(79,59)</u> , <i>c</i>	 <i>a</i> , (67,55), <i>b</i> , <u>(79,59)</u> , <i>c</i> , <u>(45,29)</u> , <i>d</i>	
from <i>b</i> ...	 <i>b</i> , <u>(79,59)</u> , <i>c</i> , <u>(36,28)</u> , <i>a</i>	---	 <i>b</i> , <u>(79,59)</u> , <i>c</i>	 <i>b</i> , <u>(79,59)</u> , <i>c</i> , <u>(45,29)</u> , <i>d</i>	
from <i>c</i> ...	 <i>c</i> , <u>(36,28)</u> , <i>a</i>	 <i>c</i> , (36,28), <i>a</i> , <u>(67,55)</u> , <i>b</i>	---	 <i>c</i> , <u>(45,29)</u> , <i>d</i>	
from <i>d</i> ...	 <i>d</i> , <u>(50,40)</u> , <i>a</i>	 <i>d</i> , (50,40), <i>a</i> , <u>(67,55)</u> , <i>b</i>	 <i>d</i> , (50,40), <i>a</i> , <u>(67,55)</u> , <i>b</i> , <u>(79,59)</u> , <i>c</i>	---	
from every other alternative ...					---

The strengths of the strongest paths are:

	$P_{los}[* ,a]$	$P_{los}[* ,b]$	$P_{los}[* ,c]$	$P_{los}[* ,d]$
$P_{los}[a,*]$	---	(67,55)	(79,59)	(79,59)
$P_{los}[b,*]$	(79,59)	---	(79,59)	(79,59)
$P_{los}[c,*]$	(36,28)	(67,55)	---	(45,29)
$P_{los}[d,*]$	(50,40)	(67,55)	(79,59)	---

We get $O_{los} = \{ab, ca, cb, cd, da, db\}$ and $S_{los} = \{c\}$.

Suppose, the strongest paths are calculated with the Floyd-Warshall algorithm, as defined in section 2.3.1. Then the following table documents the $C \cdot (C-1) \cdot (C-2) = 24$ steps of the Floyd-Warshall algorithm.

We start with

- $P_{los}[i,j] := (N[i,j], N[j,i])$ for all $i \in A$ and $j \in A \setminus \{i\}$.
- $pred[i,j] := i$ for all $i \in A$ and $j \in A \setminus \{i\}$.

	i	j	k	$P_{los}[j,k]$	$P_{los}[j,i]$	$P_{los}[i,k]$	$pred[j,k]$	$pred[i,k]$	result
1	a	b	c	(79,59)	(55,67)	(28,36)	b	a	
2	a	b	d	(58,72)	(55,67)	(40,50)	b	a	
3	a	c	b	(59,79)	(36,28)	(67,55)	c	a	$P_{los}[c,b]$ is updated from (59,79) to (67,55); $pred[c,b]$ is updated from c to a .
4	a	c	d	(45,29)	(36,28)	(40,50)	c	a	
5	a	d	b	(72,58)	(50,40)	(67,55)	d	a	$P_{los}[d,b]$ is updated from (72,58) to (67,55); $pred[d,b]$ is updated from d to a .

3.11. Example 11

Example 11:

9 voters $a \succ_v d \succ_v b \succ_v e \succ_v c$
 6 voters $b \succ_v c \succ_v a \succ_v d \succ_v e$
 5 voters $b \succ_v c \succ_v d \succ_v e \succ_v a$
 2 voters $c \succ_v d \succ_v b \succ_v e \succ_v a$
 6 voters $d \succ_v e \succ_v c \succ_v b \succ_v a$
 14 voters $e \succ_v a \succ_v c \succ_v b \succ_v d$
 2 voters $e \succ_v c \succ_v a \succ_v b \succ_v d$
 1 voter $e \succ_v d \succ_v a \succ_v c \succ_v b$

The pairwise matrix N looks as follows:

	$N[*,a]$	$N[*,b]$	$N[*,c]$	$N[*,d]$	$N[*,e]$
$N[a,*]$	---	26	24	31	15
$N[b,*]$	19	---	20	27	22
$N[c,*]$	21	25	---	29	13
$N[d,*]$	14	18	16	---	28
$N[e,*]$	30	23	32	17	---

The corresponding digraph looks as follows:

The following table lists the strongest paths, as determined by the Floyd-Warshall algorithm, as defined in section 2.3.1. The critical links of the strongest paths are underlined:

	... to <i>a</i>	... to <i>b</i>	... to <i>c</i>	... to <i>d</i>	... to <i>e</i>
from <i>a</i> ...	---	<i>a</i> , <u>(26,19)</u> , <i>b</i>	<i>a</i> , (31,14), <i>d</i> , <u>(28,17)</u> , <i>e</i> , (32,13), <i>c</i>	<i>a</i> , <u>(31,14)</u> , <i>d</i>	<i>a</i> , (31,14), <i>d</i> , <u>(28,17)</u> , <i>e</i>
from <i>b</i> ...	<i>b</i> , <u>(27,18)</u> , <i>d</i> , (28,17), <i>e</i> , (30,15), <i>a</i>	---	<i>b</i> , <u>(27,18)</u> , <i>d</i> , (28,17), <i>e</i> , (32,13), <i>c</i>	<i>b</i> , <u>(27,18)</u> , <i>d</i>	<i>b</i> , <u>(27,18)</u> , <i>d</i> , (28,17), <i>e</i>
from <i>c</i> ...	<i>c</i> , (29,16), <i>d</i> , <u>(28,17)</u> , <i>e</i> , (30,15), <i>a</i>	<i>c</i> , (29,16), <i>d</i> , (28,17), <i>e</i> , (30,15), <i>a</i> , <u>(26,19)</u> , <i>b</i>	---	<i>c</i> , <u>(29,16)</u> , <i>d</i>	<i>c</i> , (29,16), <i>d</i> , <u>(28,17)</u> , <i>e</i>
from <i>d</i> ...	<i>d</i> , <u>(28,17)</u> , <i>e</i> , (30,15), <i>a</i>	<i>d</i> , (28,17), <i>e</i> , (30,15), <i>a</i> , <u>(26,19)</u> , <i>b</i>	<i>d</i> , <u>(28,17)</u> , <i>e</i> , (32,13), <i>c</i>	---	<i>d</i> , <u>(28,17)</u> , <i>e</i>
from <i>e</i> ...	<i>e</i> , <u>(30,15)</u> , <i>a</i>	<i>e</i> , (30,15), <i>a</i> , <u>(26,19)</u> , <i>b</i>	<i>e</i> , <u>(32,13)</u> , <i>c</i>	<i>e</i> , <u>(30,15)</u> , <i>a</i> , (31,14), <i>d</i>	---

The strongest path from a to b is:
 a , (26,19), b

The strongest path from a to c is:
 a , (31,14), d , (28,17), e , (32,13), c

The strongest path from a to d is:
 a , (31,14), d

The strongest path from a to e is:
 a , (31,14), d , (28,17), e

These are the strongest paths
 from a to every other alternative.

The strongest path from b to a is:
 b , $(27,18)$, d , $(28,17)$, e , $(30,15)$, a

The strongest path from b to c is:
 b , $(27,18)$, d , $(28,17)$, e , $(32,13)$, c

The strongest path from b to d is:
 b , $(27,18)$, d

The strongest path from b to e is:
 b , $(27,18)$, d , $(28,17)$, e

These are the strongest paths
 from b to every other alternative.

The strongest path from c to a is:
 c , (29,16), d , (28,17), e , (30,15), a

The strongest path from c to b is:
 c , (29,16), d , (28,17), e ,
 (30,15), a , (26,19), b

The strongest path from c to d is:
 c , (29,16), d

The strongest path from c to e is:
 c , (29,16), d , (28,17), e

These are the strongest paths
 from c to every other alternative.

The strongest path from d to a is:
 d , $(28,17)$, e , $(30,15)$, a

The strongest path from d to b is:
 d , $(28,17)$, e , $(30,15)$, a , $(26,19)$, b

The strongest path from d to c is:
 d , $(28,17)$, e , $(32,13)$, c

The strongest path from d to e is:
 d , $(28,17)$, e

These are the strongest paths
 from d to every other alternative.

The strongest path from e to a is:
 $e, (30,15), a$

The strongest path from e to b is:
 $e, (30,15), a, (26,19), b$

The strongest path from e to c is:
 $e, (32,13), c$

The strongest path from e to d is:
 $e, (30,15), a, (31,14), d$

These are the strongest paths
 from e to every other alternative.

These are the strongest paths from every other alternative to a .

These are the strongest paths from every other alternative to b .

These are the strongest paths from every other alternative to c .

These are the strongest paths from every other alternative to d .

These are the strongest paths from every other alternative to e .

Therefore, the strengths of the strongest paths are:

	$P_D[*,a]$	$P_D[*,b]$	$P_D[*,c]$	$P_D[*,d]$	$P_D[*,e]$
$P_D[a,*]$	---	(26,19)	(28,17)	(31,14)	(28,17)
$P_D[b,*]$	(27,18)	---	(27,18)	(27,18)	(27,18)
$P_D[c,*]$	(28,17)	(26,19)	---	(29,16)	(28,17)
$P_D[d,*]$	(28,17)	(26,19)	(28,17)	---	(28,17)
$P_D[e,*]$	(30,15)	(26,19)	(32,13)	(30,15)	---

We get $O = \{ad, ba, bc, bd, be, cd, ea, ec, ed\}$ and $S = \{b\}$.

Suppose, the strongest paths are calculated with the Floyd-Warshall algorithm, as defined in section 2.3.1. Then the following table documents the $C \cdot (C-1) \cdot (C-2) = 60$ steps of the Floyd-Warshall algorithm.

We start with

- $P_D[i,j] := (N[i,j], N[j,i])$ for all $i \in A$ and $j \in A \setminus \{i\}$.
- $pred[i,j] := i$ for all $i \in A$ and $j \in A \setminus \{i\}$.

	i	j	k	$P_D[j,k]$	$P_D[j,i]$	$P_D[i,k]$	$pred[j,k]$	$pred[i,k]$	result
1	a	b	c	(20,25)	(19,26)	(24,21)	b	a	
2	a	b	d	(27,18)	(19,26)	(31,14)	b	a	
3	a	b	e	(22,23)	(19,26)	(15,30)	b	a	
4	a	c	b	(25,20)	(21,24)	(26,19)	c	a	
5	a	c	d	(29,16)	(21,24)	(31,14)	c	a	
6	a	c	e	(13,32)	(21,24)	(15,30)	c	a	$P_D[c,e]$ is updated from (13,32) to (15,30); $pred[c,e]$ is updated from c to a .
7	a	d	b	(18,27)	(14,31)	(26,19)	d	a	
8	a	d	c	(16,29)	(14,31)	(24,21)	d	a	
9	a	d	e	(28,17)	(14,31)	(15,30)	d	a	
10	a	e	b	(23,22)	(30,15)	(26,19)	e	a	$P_D[e,b]$ is updated from (23,22) to (26,19); $pred[e,b]$ is updated from e to a .
11	a	e	c	(32,13)	(30,15)	(24,21)	e	a	
12	a	e	d	(17,28)	(30,15)	(31,14)	e	a	$P_D[e,d]$ is updated from (17,28) to (30,15); $pred[e,d]$ is updated from e to a .
13	b	a	c	(24,21)	(26,19)	(20,25)	a	b	
14	b	a	d	(31,14)	(26,19)	(27,18)	a	b	
15	b	a	e	(15,30)	(26,19)	(22,23)	a	b	$P_D[a,e]$ is updated from (15,30) to (22,23); $pred[a,e]$ is updated from a to b .
16	b	c	a	(21,24)	(25,20)	(19,26)	c	b	
17	b	c	d	(29,16)	(25,20)	(27,18)	c	b	
18	b	c	e	(15,30)	(25,20)	(22,23)	a	b	$P_D[c,e]$ is updated from (15,30) to (22,23); $pred[c,e]$ is updated from a to b .
19	b	d	a	(14,31)	(18,27)	(19,26)	d	b	$P_D[d,a]$ is updated from (14,31) to (18,27); $pred[d,a]$ is updated from d to b .
20	b	d	c	(16,29)	(18,27)	(20,25)	d	b	$P_D[d,c]$ is updated from (16,29) to (18,27); $pred[d,c]$ is updated from d to b .
21	b	d	e	(28,17)	(18,27)	(22,23)	d	b

from <i>d</i> ...	<i>d</i> , <u>(28,17)</u> , <i>e</i> , (29,16), <i>a</i>	<i>d</i> , (28,17), <i>e</i> , <u>(27,18)</u> , <i>b</i>	<i>d</i> , <u>(28,17)</u> , <i>e</i> , (31,14), <i>c</i>	---	<i>d</i> , <u>(28,17)</u> , <i>e</i>
from <i>e</i> ...	<i>e</i> , <u>(29,16)</u> , <i>a</i>	<i>e</i> , <u>(27,18)</u> , <i>b</i>	<i>e</i> , <u>(31,14)</u> , <i>c</i>	<i>e</i> , (31,14), <i>c</i> , <u>(30,15)</u> , <i>d</i>	---

The strongest path from a to b is:
 a , (32,13), d , (28,17), e , (27,18), b

The strongest path from a to c is:
 a , (32,13), d , (28,17), e , (31,14), c

The strongest path from a to d is:
 a , (32,13), d

The strongest path from a to e is:
 a , (32,13), d , (28,17), e

These are the strongest paths
 from a to every other alternative.

The strongest path from b to a is:
 b , $(26,19)$, c , $(30,15)$, d ,
 $(28,17)$, e , $(29,16)$, a

The strongest path from b to c is:
 b , $(26,19)$, c

The strongest path from b to d is:
 b , $(26,19)$, c , $(30,15)$, d

The strongest path from b to e is:
 b , $(26,19)$, c , $(30,15)$, d , $(28,17)$, e

These are the strongest paths
 from b to every other alternative.

The strongest path from c to a is:
 c , (30,15), d , (28,17), e , (29,16), a

The strongest path from c to b is:
 c , (30,15), d , (28,17), e , (27,18), b

The strongest path from c to d is:
 c , (30,15), d

The strongest path from c to e is:
 c , (30,15), d , (28,17), e

These are the strongest paths
 from c to every other alternative.

The strongest path from d to a is:
 d , $(\underline{28,17})$, e , $(29,16)$, a

The strongest path from d to b is:
 d , $(28,17)$, e , $(\underline{27,18})$, b

The strongest path from d to c is:
 d , $(\underline{28,17})$, e , $(31,14)$, c

The strongest path from d to e is:
 d , $(\underline{28,17})$, e

These are the strongest paths
 from d to every other alternative.

The strongest path from e to a is:
 $e, (29,16), a$

The strongest path from e to b is:
 $e, (27,18), b$

The strongest path from e to c is:
 $e, (31,14), c$

The strongest path from e to d is:
 $e, (31,14), c, (30,15), d$

These are the strongest paths
 from e to every other alternative.

These are the strongest paths from every other alternative to a .

These are the strongest paths from every other alternative to b .

These are the strongest paths from every other alternative to c .

These are the strongest paths from every other alternative to d .

These are the strongest paths from every other alternative to e .

Therefore, the strengths of the strongest paths are:

	$P_D[*,a]$	$P_D[*,b]$	$P_D[*,c]$	$P_D[*,d]$	$P_D[*,e]$
$P_D[a,*]$	---	(27,18)	(28,17)	(32,13)	(28,17)
$P_D[b,*]$	(26,19)	---	(26,19)	(26,19)	(26,19)
$P_D[c,*]$	(28,17)	(27,18)	---	(30,15)	(28,17)
$P_D[d,*]$	(28,17)	(27,18)	(28,17)	---	(28,17)
$P_D[e,*]$	(29,16)	(27,18)	(31,14)	(30,15)	---

We get $O = \{ab, ad, cb, cd, db, ea, eb, ec, ed\}$ and $S = \{e\}$.

Suppose, the strongest paths are calculated with the Floyd-Warshall algorithm, as defined in section 2.3.1. Then the following table documents the $C \cdot (C-1) \cdot (C-2) = 60$ steps of the Floyd-Warshall algorithm.

We start with

- $P_D[i,j] := (N[i,j], N[j,i])$ for all $i \in A$ and $j \in A \setminus \{i\}$.
- $pred[i,j] := i$ for all $i \in A$ and $j \in A \setminus \{i\}$.

	i	j	k	$P_D[j,k]$	$P_D[j,i]$	$P_D[i,k]$	$pred[j,k]$	$pred[i,k]$	result
1	a	b	c	(26,19)	(25,20)	(24,21)	b	a	
2	a	b	d	(23,22)	(25,20)	(32,13)	b	a	$P_D[b,d]$ is updated from (23,22) to (25,20); $pred[b,d]$ is updated from b to a .
3	a	b	e	(18,27)	(25,20)	(16,29)	b	a	
4	a	c	b	(19,26)	(21,24)	(20,25)	c	a	$P_D[c,b]$ is updated from (19,26) to (20,25); $pred[c,b]$ is updated from c to a .
5	a	c	d	(30,15)	(21,24)	(32,13)	c	a	
6	a	c	e	(14,31)	(21,24)	(16,29)	c	a	$P_D[c,e]$ is updated from (14,31) to (16,29); $pred[c,e]$ is updated from c to a .
7	a	d	b	(22,23)	(13,32)	(20,25)	d	a	
8	a	d	c	(15,30)	(13,32)	(24,21)	d	a

3.13. Example 13

Example 13:

2 voters $a \succ_v b \succ_v c$
2 voters $b \succ_v c \succ_v a$
1 voter $c \succ_v a \succ_v b$

The pairwise matrix N looks as follows:

	$N[*,a]$	$N[*,b]$	$N[*,c]$
$N[a,*]$	---	3	2
$N[b,*]$	2	---	4
$N[c,*]$	3	1	---

The corresponding digraph looks as follows:

The following table lists the strongest paths, as determined by the Floyd-Warshall algorithm, as defined in section 2.3.1. The critical links of the strongest paths are underlined:

	... to a	... to b	... to c	... to every other alternative
from a ...	---	 $a, \underline{(3,2)}, b$	 $a, \underline{(3,2)}, b, \underline{(4,1)}, c$	
from b ...	 $b, \underline{(4,1)}, c, \underline{(3,2)}, a$	---	 $b, \underline{(4,1)}, a, \underline{(3,2)}, c$	
from c ...	 $c, \underline{(3,2)}, b, \underline{(4,1)}, a$	 $c, \underline{(3,2)}, a, \underline{(3,2)}, b$	---	
from every other alternative ...				---

The strengths of the strongest paths are:

	$P_D[*,a]$	$P_D[*,b]$	$P_D[*,c]$
$P_D[a,*]$	---	(3,2)	(3,2)
$P_D[b,*]$	(3,2)	---	(4,1)
$P_D[c,*]$	(3,2)	(3,2)	---

We get $O = \{bc\}$ and $S = \{a, b\}$.

Suppose, the strongest paths are calculated with the Floyd-Warshall algorithm, as defined in section 2.3.1. Then the following table documents the $C \cdot (C-1) \cdot (C-1) = 6$ steps of the Floyd-Warshall algorithm.

We start with

- $P_D[i,j] := (N[i,j], N[j,i])$ for all $i \in A$ and $j \in A \setminus \{i\}$.
- $pred[i,j] := i$ for all $i \in A$ and $j \in A \setminus \{i\}$.

	i	j	k	$P_D[j,k]$	$P_D[j,i]$	$P_D[i,k]$	$pred[j,k]$	$pred[i,k]$	result
1	a	b	c	(4,1)	(2,3)	(2,3)	b	a	
2	a	c	b	(1,4)	(3,2)	(3,2)	c	a	$P_D[c,b]$ is updated from (1,4) to (3,2); $pred[c,b]$ is updated from c to a .
3	b	a	c	(2,3)	(3,2)	(4,1)	a	b	$P_D[a,c]$ is updated from (2,3) to (3,2); $pred[a,c]$ is updated from a to b .
4	b	c	a	(3,2)	(3,2)	(2,3)	c	b	
5	c	a	b	(3,2)	(3,2)	(3,2)	a	a	
6	c	b	a	(2,3)	(4,1)	(3,2)	b	c	$P_D[b,a]$ is updated from (2,3) to (3,2); $pred[b,a]$ is updated from b to c .

3.14. Example 14

Example 14:

1 voter $a \succ_v b \succ_v d \succ_v e \succ_v c \succ_v f$
11 voters $a \succ_v b \succ_v e \succ_v f \succ_v c \succ_v d$
5 voters $a \succ_v d \succ_v b \succ_v e \succ_v c \succ_v f$
12 voters $a \succ_v e \succ_v f \succ_v d \succ_v b \succ_v c$
7 voters $b \succ_v c \succ_v f \succ_v a \succ_v d \succ_v e$
1 voter $c \succ_v a \succ_v f \succ_v b \succ_v d \succ_v e$
15 voters $c \succ_v b \succ_v f \succ_v d \succ_v a \succ_v e$
3 voters $c \succ_v d \succ_v b \succ_v a \succ_v e \succ_v f$
3 voters $c \succ_v d \succ_v b \succ_v f \succ_v a \succ_v e$
2 voters $d \succ_v c \succ_v a \succ_v b \succ_v e \succ_v f$
11 voters $d \succ_v c \succ_v f \succ_v b \succ_v e \succ_v a$
14 voters $d \succ_v e \succ_v f \succ_v a \succ_v b \succ_v c$
1 voter $e \succ_v c \succ_v f \succ_v d \succ_v b \succ_v a$
5 voters $e \succ_v f \succ_v b \succ_v c \succ_v a \succ_v d$
5 voters $e \succ_v f \succ_v c \succ_v d \succ_v a \succ_v b$
1 voter $f \succ_v a \succ_v d \succ_v b \succ_v e \succ_v c$

The pairwise matrix N looks as follows:

	$N[*,a]$	$N[*,b]$	$N[*,c]$	$N[*,d]$	$N[*,e]$	$N[*,f]$
$N[a,*]$	---	52	44	43	61	35
$N[b,*]$	45	---	56	40	60	47
$N[c,*]$	53	41	---	51	42	49
$N[d,*]$	54	57	46	---	63	39
$N[e,*]$	36	37	55	34	---	59
$N[f,*]$	62	50	48	58	38	---

The corresponding digraph looks as follows:

The following table lists the strongest paths, as determined by the Floyd-Warshall algorithm, as defined in section 2.3.1. The critical links of the strongest paths are underlined:

	... to <i>a</i>	... to <i>b</i>	... to <i>c</i>	... to <i>d</i>	... to <i>e</i>	... to <i>f</i>
from <i>a</i> ...	---	<i>a</i> , (61,36), <i>e</i> , (59,38), <i>f</i> , (58,39), <i>d</i> , <u>(57,40)</u> , <i>b</i>	<i>a</i> , (61,36), <i>e</i> , (59,38), <i>f</i> , (58,39), <i>d</i> , (57,40), <i>b</i> , <u>(56,41)</u> , <i>c</i>	<i>a</i> , (61,36), <i>e</i> , (59,38), <i>f</i> , <u>(58,39)</u> , <i>d</i>	<i>a</i> , <u>(61,36)</u> , <i>e</i>	<i>a</i> , (61,36), <i>e</i> , <u>(59,38)</u> , <i>f</i>

from <i>f</i> ...	<i>f</i> , <u>(62,35)</u> , <i>a</i>	<i>f</i> , (58,39), <i>d</i> , <u>(57,40)</u> , <i>b</i>	<i>f</i> , (58,39), <i>d</i> , (57,40), <i>b</i> , <u>(56,41)</u> , <i>c</i>	<i>f</i> , <u>(58,39)</u> , <i>d</i>	<i>f</i> , (62,35), <i>a</i> , <u>(61,36)</u> , <i>e</i>	---

The strongest path from a to b is:
 a , $(61,36)$, e , $(59,38)$, f , $(58,39)$, d ,
 $(57,40)$, b

The strongest path from a to c is:
 a , $(61,36)$, e , $(59,38)$, f , $(58,39)$, d ,
 $(57,40)$, b , $(56,41)$, c

The strongest path from a to d is:
 a , $(61,36)$, e , $(59,38)$, f , $(58,39)$, d

The strongest path from a to e is:
 a , $(61,36)$, e

The strongest path from a to f is:
 a , $(61,36)$, e , $(59,38)$, f

These are the strongest paths
 from a to every other alternative.

The strongest path from b to a is:
 b , $(60,37)$, e , $(59,38)$, f , $(62,35)$, a

The strongest path from b to c is:
 b , $(56,41)$, c

The strongest path from b to d is:
 b , $(60,37)$, e , $(59,38)$, f , $(58,39)$, d

The strongest path from b to e is:
 b , $(60,37)$, e

The strongest path from b to f is:
 b , $(60,37)$, e , $(59,38)$, f

These are the strongest paths
 from b to every other alternative.

The strongest path from c to a is:
 $c, \underline{(53,44)}, a$

The strongest path from c to b is:
 $c, \underline{(53,44)}, a, (61,36), e, (59,38), f, (58,39), d, (57,40), b$

The strongest path from c to d is:
 $c, \underline{(53,44)}, a, (61,36), e, (59,38), f, (58,39), d$

The strongest path from c to e is:
 $c, \underline{(53,44)}, a, (61,36), e$

The strongest path from c to f is:
 $c, \underline{(53,44)}, a, (61,36), e, (59,38), f$

These are the strongest paths from c to every other alternative.

The strongest path from d to a is:
 d , (63,34), e , (59,38), f , (62,35), a

The strongest path from d to b is:
 d , (57,40), b

The strongest path from d to c is:
 d , (57,40), b , (56,41), c

The strongest path from d to e is:
 d , (63,34), e

The strongest path from d to f is:
 d , (63,34), e , (59,38), f

These are the strongest paths
 from d to every other alternative.

The strongest path from e to a is:
 e , $(59,38)$, f , $(62,35)$, a

The strongest path from e to b is:
 e , $(59,38)$, f , $(58,39)$, d , $(57,40)$, b

The strongest path from e to c is:
 e , $(59,38)$, f , $(58,39)$, d , $(57,40)$, b ,
 $(56,41)$, c

The strongest path from e to d is:
 e , $(59,38)$, f , $(58,39)$, d

The strongest path from e to f is:
 e , $(59,38)$, f

These are the strongest paths
from e to every other alternative.

The strongest path from f to a is:
 $f, \underline{(62,35)}, a$

The strongest path from f to b is:
 $f, (58,39), d, \underline{(57,40)}, b$

The strongest path from f to c is:
 $f, (58,39), d, (57,40), b, \underline{(56,41)}, c$

The strongest path from f to d is:
 $f, \underline{(58,39)}, d$

The strongest path from f to e is:
 $f, (62,35), a, \underline{(61,36)}, e$

These are the strongest paths from f to every other alternative.

These are the strongest paths from every other alternative to *a*.

These are the strongest paths from every other alternative to *b*.

These are the strongest paths from every other alternative to *c*.

These are the strongest paths from every other alternative to *d*.

These are the strongest paths from every other alternative to *e*.

These are the strongest paths from every other alternative to *f*.

Therefore, the strengths of the strongest paths are:

	$P_D[*,a]$	$P_D[*,b]$	$P_D[*,c]$	$P_D[*,d]$	$P_D[*,e]$	$P_D[*,f]$
$P_D[a,*]$	---	(57,40)	(56,41)	(58,39)	(61,36)	(59,38)
$P_D[b,*]$	(59,38)	---	(56,41)	(58,39)	(60,37)	(59,38)
$P_D[c,*]$	(53,44)	(53,44)	---	(53,44)	(53,44)	(53,44)
$P_D[d,*]$	(59,38)	(57,40)	(56,41)	---	(63,34)	(59,38)
$P_D[e,*]$	(59,38)	(57,40)	(56,41)	(58,39)	---	(59,38)
$P_D[f,*]$	(62,35)	(57,40)	(56,41)	(58,39)	(61,36)	---

We get $O = \{ac, ae, ba, bc, bd, be, bf, da, dc, de, df, ec, fa, fc, fe\}$ and $S = \{b\}$.

Suppose, the strongest paths are calculated with the Floyd-Warshall algorithm, as defined in section 2.3.1. Then the following table documents the $C \cdot (C-1) \cdot (C-2) = 120$ steps of the Floyd-Warshall algorithm.

We start with

- $P_D[i,j] := (N[i,j], N[j,i])$ for all $i \in A$ and $j \in A \setminus \{i\}$.
- $pred[i,j] := i$ for all $i \in A$ and $j \in A \setminus \{i\}$.

	i	j	k	$P_D[j,k]$	$P_D[j,i]$	$P_D[i,k]$	$pred[j,k]$	$pred[i,k]$	result
1	a	b	c	(56,41)	(45,52)	(44,53)	b	a	
2	a	b	d	(40,57)	(45,52)	(43,54)	b	a	$P_D[b,d]$ is updated from (40,57) to (43,54); $pred[b,d]$ is updated from b to a .
3	a	b	e	(60,37)	(45,52)	(61,36)	b	a

117	f	e	a	(53,44)	(59,38)	(62,35)	c	f	$P_D[e,a]$ is updated from (53,44) to (59,38); $pred[e,a]$ is updated from c to f .
118	f	e	b	(52,45)	(59,38)	(57,40)	a	d	$P_D[e,b]$ is updated from (52,45) to (57,40); $pred[e,b]$ is updated from a to d .
119	f	e	c	(55,42)	(59,38)	(56,41)	e	b	$P_D[e,c]$ is updated from (55,42) to (56,41); $pred[e,c]$ is updated from e to b .
120	f	e	d	(51,46)	(59,38)	(58,39)	c	f	$P_D[e,d]$ is updated from (51,46) to (58,39); $pred[e,d]$ is updated from c to f .

4. Analysis of the Schulze Method

4.1. Transitivity

In this section, we will prove that the binary relation O , as defined in (2.2.1), is *transitive*. This means: If $ab \in O$ and $bc \in O$, then $ac \in O$. This guarantees that the set S of potential winners, as defined in (2.2.2), is non-empty. When we interpret the Schulze method as a method to find a set S of potential winners, rather than a method to generate a binary relation O , then the proof of the transitivity of O is an essential part of the proof that the Schulze method is well defined.

Definition:

An election method satisfies *transitivity* if the following holds for all $a, b, c \in A$:

Suppose:

$$(4.1.1) \quad ab \in O.$$

$$(4.1.2) \quad bc \in O.$$

Then:

$$(4.1.3) \quad ac \in O.$$

Claim:

The binary relation O , as defined in (2.2.1), is transitive.

Proof:

With (4.1.1), we get

$$(4.1.4) \quad P_D[a, b] >_D P_D[b, a].$$

With (4.1.2), we get

$$(4.1.5) \quad P_D[b, c] >_D P_D[c, b].$$

With (2.2.5), we get

$$(4.1.6) \quad \min_D \{ P_D[a,b], P_D[b,c] \} \lesssim_D P_D[a,c].$$

$$(4.1.7) \quad \min_D \{ P_D[b,c], P_D[c,a] \} \lesssim_D P_D[b,a].$$

$$(4.1.8) \quad \min_D \{ P_D[c,a], P_D[a,b] \} \lesssim_D P_D[c,b].$$

Case 1: Suppose

$$(4.1.9a) \quad P_D[a,b] \gtrsim_D P_D[b,c].$$

Combining (4.1.5) and (4.1.9a) gives

$$(4.1.10a) \quad P_D[a,b] \succ_D P_D[c,b].$$

Combining (4.1.8) and (4.1.10a) gives

$$(4.1.11a) \quad P_D[c,a] \lesssim_D P_D[c,b].$$

Combining (4.1.6) and (4.1.9a) gives

$$(4.1.12a) \quad P_D[b,c] \lesssim_D P_D[a,c].$$

Combining (4.1.11a), (4.1.5), and (4.1.12a) gives

$$(4.1.13a) \quad P_D[c,a] \lesssim_D P_D[c,b] \prec_D P_D[b,c] \lesssim_D P_D[a,c].$$

With (4.1.13a), we get (4.1.3).

Case 2: Suppose

$$(4.1.9b) \quad P_D[a,b] \prec_D P_D[b,c].$$

Combining (4.1.4) and (4.1.9b) gives

$$(4.1.10b) \quad P_D[b,a] \prec_D P_D[b,c].$$

Combining (4.1.7) and (4.1.10b) gives

$$(4.1.11b) \quad P_D[c,a] \lesssim_D P_D[b,a].$$

Combining (4.1.6) and (4.1.9b) gives

$$(4.1.12b) \quad P_D[a,b] \lesssim_D P_D[a,c].$$

Combining (4.1.11b), (4.1.4), and (4.1.12b) gives

$$(4.1.13b) \quad P_D[c,a] \lesssim_D P_D[b,a] \prec_D P_D[a,b] \lesssim_D P_D[a,c].$$

With (4.1.13b), we get (4.1.3). $\square$

The proof, that the Schulze method is transitive, has first been published by Schulze (1998b, 2003, 2011a). This proof can also be found in papers by Tideman (2006), Camps (2008, 2012b), Börgers (2009), and Duchin (2021, [04:26:14 – 05:05:10 hh:mm:ss](#)).

In example 4 (section 3.4), we have $ba \notin \mathcal{O}$ and $ac \notin \mathcal{O}$ and $bc \in \mathcal{O}$. This shows that the Schulze relation, as defined in (2.2.1), is not necessarily negatively transitive.

The following corollary says that the set $\mathcal{S}$ of potential winners, as defined in (2.2.2), is non-empty.

Corollary (4.1.14):

For the Schulze method, as defined in section 2.2, we get

$$(4.1.14) \quad \forall b \notin \mathcal{S} \exists a \in \mathcal{S}: ab \in \mathcal{O}.$$

Proof of corollary (4.1.14):

As $b \notin \mathcal{S}$, there must be a $c(1) \in A$ with $c(1), b \in \mathcal{O}$.

If $c(1) \in \mathcal{S}$, then the corollary is proven. If $c(1) \notin \mathcal{S}$, then there must be a $c(2) \in A$ with $c(2), c(1) \in \mathcal{O}$. With the asymmetry and the transitivity of $\mathcal{O}$, we get $c(2), b \in \mathcal{O}$ and $c(2) \notin \{b, c(1)\}$.

We now proceed as follows: If $c(i) \in \mathcal{S}$, then the corollary is proven. If $c(i) \notin \mathcal{S}$, then there must be a $c(i+1) \in A$ with $c(i+1), c(i) \in \mathcal{O}$. With the asymmetry and the transitivity of $\mathcal{O}$, we get $c(i+1), b \in \mathcal{O}$ and $c(i+1) \notin \{b, c(1), \dots, c(i)\}$.

We proceed until $c(i) \in \mathcal{S}$ for some $i \in \mathbb{N}$. Such an $i \in \mathbb{N}$ exists because A is finite. $\square$

The following corollary says that alternative $a \in A$ is the unique winner if and only if alternative a disqualifies every other alternative $b \in A \setminus \{a\}$.

Corollary (4.1.15):

For the Schulze method, as defined in section 2.2, we get

$$(4.1.15) \quad \mathcal{S} = \{a\} \Leftrightarrow (\forall b \in A \setminus \{a\}: ab \in \mathcal{O}).$$

Proof of corollary (4.1.15):

$\Leftarrow$ If $ab \in \mathcal{O} \forall b \in A \setminus \{a\}$, then $a \in A$ disqualifies every $b \in A \setminus \{a\}$ according to (2.2.2). Therefore, we get $\mathcal{S} = \{a\}$.

$\Rightarrow$ With (4.1.14) and $\mathcal{S} = \{a\}$, we get

$$(4.1.16) \quad \forall b \notin \mathcal{S}: ab \in \mathcal{O}.$$

With $\mathcal{S} = \{a\}$, we get

$$(4.1.17) \quad b \notin \mathcal{S} \Leftrightarrow b \in A \setminus \{a\}.$$

With (4.1.16) and (4.1.17), we get

$$(4.1.18) \quad \forall b \in A \setminus \{a\}: ab \in \mathcal{O}. \quad \square$$

4.2. Decisiveness

Decisiveness basically says that usually there is a unique winner $S = \{a\}$. This criterion is immensely important because — although in theory, the sole purpose of a single-winner election is to fill a single seat — in real life, a single-winner election also serves other purposes. For example, one purpose of an election is to settle a dispute, at least temporarily. Another purpose is to give the winner the legitimacy he needs to run his office successfully. For example, when in a referendum the winning option is chosen by a random choice, then the supporters of the losing option will immediately request a re-vote. And a president who is elected by a random choice will be denied any legitimacy and will be quite unable to exercise his office.

Definition:

An election method satisfies *decisiveness* if (for every given number of alternatives) the proportion of profiles without a unique winner tends to zero as the number of voters in the profile tends to infinity.

Claim:

If $>_D$ satisfies (2.1.1), then the Schulze method, as defined in section 2.2, satisfies decisiveness.

Proof (overview):

Suppose $(x_1, x_2), (y_1, y_2) \in \mathbb{N}_0 \times \mathbb{N}_0$. Then, according to (2.1.1), there is a $v_1 \in \mathbb{N}_0$ such that for all $w_1 \in \mathbb{N}_0$:

1. $w_1 < v_1 \Rightarrow (x_1, x_2) >_D (w_1, y_2)$.
2. $w_1 > v_1 \Rightarrow (x_1, x_2) <_D (w_1, y_2)$.

When the number of voters tends to infinity (i.e. when x_1, x_2, y_1 , and y_2 become large), then the proportion of profiles, where the condition “ $y_1 = v_1$ ” happens to be satisfied, tends to zero. Therefore, when the number of voters tends to infinity, then the proportion of profiles, where two links ef and gh happen to have equivalent strengths $(N[e, f], N[f, e]) \approx_D (N[g, h], N[h, g])$, tends to zero.

Therefore, we will prove that, unless there are links ef and gh of equivalent strengths, there is always a unique winner. We will prove this by showing that, when we simultaneously presume (a) that there is more than one potential winner and (b) that there are no links ef and gh of equivalent strengths, then we necessarily get to a contradiction.

Proof (details):

Suppose that there is more than one potential winner. Suppose alternative $a \in A$ and alternative $b \in A$ are potential winners. Then

$$(4.2.1) \quad \forall i \in A \setminus \{a\}: P_D[a,i] \approx_D P_D[i,a].$$

$$(4.2.2) \quad \forall j \in A \setminus \{b\}: P_D[b,j] \approx_D P_D[j,b].$$

$$(4.2.3) \quad P_D[a,b] \approx_D P_D[b,a].$$

Suppose there are no links ef and gh of equivalent strengths ($N[e,f], N[f,e]$) $\approx_D$ ($N[g,h], N[h,g]$). Then $P_D[a,b] \approx_D P_D[b,a]$ means that the weakest link in the strongest path from alternative a to alternative b and the weakest link in the strongest path from alternative b to alternative a must be the same link, say cd . Therefore, the strongest paths have the following structure:

As cd is the weakest link in the strongest path from alternative a to alternative b , we get

$$(4.2.4) \quad P_D[a,d] \approx_D P_D[a,b].$$

$$(4.2.5) \quad P_D[d,b] >_D P_D[a,b].$$

As cd is the weakest link in the strongest path from alternative b to alternative a , we get

$$(4.2.6) \quad P_D[b,d] \approx_D P_D[b,a].$$

$$(4.2.7) \quad P_D[d,a] >_D P_D[b,a].$$

With (4.2.7), (4.2.3), and (4.2.4), we get

$$(4.2.8) \quad P_D[d,a] >_D P_D[b,a] \approx_D P_D[a,b] \approx_D P_D[a,d].$$

But (4.2.8) contradicts (4.2.1).

Similarly, with (4.2.5), (4.2.3), and (4.2.6), we get

$$(4.2.9) \quad P_D[d,b] >_D P_D[a,b] \approx_D P_D[b,a] \approx_D P_D[b,d].$$

But (4.2.9) contradicts (4.2.2). □

When $>_D$ satisfies (2.1.1), then the more detailed definition for the Schulze method, as given in (5.1.6) – (5.1.7), also satisfies the following criterion: For every given number of alternatives, the proportion of profiles where $\mathcal{O}$ is not a unique linear order tends to zero as the number of voters in the profile tends to infinity. See section 5.3.2.

4.3. Resolvability

The *resolvability criterion* says that, when there is more than one potential winner, then, for every alternative $a \in \mathcal{S}$, it is sufficient to add a single ballot w so that alternative a becomes the unique winner.

Definition:

An election method satisfies *resolvability* if the following holds:

$\forall a \in \mathcal{S}^{\text{old}}$: It is possible to construct a strict weak order w with the following two properties:

$$(4.3.1) \quad \forall f \in A \setminus \{a\}: a \succ_w f.$$

$$(4.3.2) \quad \mathcal{S}^{\text{new}} = \{a\} \text{ for } \mathcal{V}^{\text{new}} := \mathcal{V}^{\text{old}} + \{w\}.$$

Claim:

If $\succ_D$ satisfies (2.1.1), then the Schulze method, as defined in section 2.2, satisfies resolvability.

Proof:

Suppose $a \in \mathcal{S}^{\text{old}}$. Then we get

$$(4.3.3) \quad \forall b \in A \setminus \{a\}: P_D^{\text{old}}[a, b] \gtrsim_D P_D^{\text{old}}[b, a].$$

Suppose $\text{pred}^{\text{old}}[x, y]$ is the predecessor of alternative y in the strongest path from alternative $x \in A$ to alternative $y \in A \setminus \{x\}$, as calculated in section 2.3.1.

Suppose the strict weak order w is chosen as follows:

$$(4.3.4) \quad \forall f \in A \setminus \{a\}: \text{pred}^{\text{old}}[a, f] \succ_w f.$$

$$(4.3.5) \quad \forall e, f \in A \setminus \{a\}: (P_D^{\text{old}}[e, a] \succ_D P_D^{\text{old}}[f, a] \Rightarrow e \succ_w f).$$

With (4.3.4), we get (4.3.1).

We will prove the following three claims:

Claim #1: It is not possible that (4.3.4) requires $e \succ_w f$ and that simultaneously (4.3.5) requires $f \succ_w e$.

Claim #2: $\forall g \in A \setminus \{a\}: P_D^{\text{new}}[a, g] \succ_D P_D^{\text{old}}[a, g]$.

Claim #3: $\forall g \in A \setminus \{a\}: P_D^{\text{new}}[g, a] \prec_D P_D^{\text{old}}[g, a]$.

With claim #2 and claim #3, we get

$$P_D^{\text{new}}[a, g] \succ_D P_D^{\text{new}}[g, a] \text{ for all } g \in A \setminus \{a\}$$

so that $ag \in \mathcal{O}^{\text{new}}$ for all $g \in A \setminus \{a\}$

so that $\mathcal{S}^{\text{new}} = \{a\}$.

Proof of claim #1:

Suppose $e, f \in A \setminus \{a\}$. With (2.2.3), we get

$$(4.3.6) \quad P_D^{\text{old}}[e, f] \approx_D (N^{\text{old}}[e, f], N^{\text{old}}[f, e]).$$

With (2.2.5), we get

$$(4.3.7) \quad \min_D \{ P_D^{\text{old}}[e, f], P_D^{\text{old}}[f, a] \} \lesssim_D P_D^{\text{old}}[e, a].$$

With (4.3.3), we get

$$(4.3.8) \quad P_D^{\text{old}}[a, f] \approx_D P_D^{\text{old}}[f, a].$$

Suppose (4.3.4) requires $e \succ_w f$. Then $e = \text{pred}^{\text{old}}[a, f]$. Therefore, the link ef was in the strongest path from alternative a to alternative f . Thus, we get

$$(4.3.9) \quad P_D^{\text{old}}[a, f] \lesssim_D (N^{\text{old}}[e, f], N^{\text{old}}[f, e]).$$

Suppose (4.3.5) requires $f \succ_w e$. Then

$$(4.3.10) \quad P_D^{\text{old}}[f, a] \succ_D P_D^{\text{old}}[e, a].$$

With (4.3.6), (4.3.9), (4.3.8), and (4.3.10), we get

$$(4.3.11) \quad P_D^{\text{old}}[e, f] \approx_D (N^{\text{old}}[e, f], N^{\text{old}}[f, e]) \approx_D P_D^{\text{old}}[a, f] \approx_D P_D^{\text{old}}[f, a] \succ_D P_D^{\text{old}}[e, a].$$

But (4.3.10) and (4.3.11) together contradict (4.3.7).

Proof of claim #2:

With (2.1.1) and (4.3.4), we get: The strength of each link of the strongest paths from alternative a to each other alternative $g \in A \setminus \{a\}$ is increased. Therefore

$$(4.3.12) \quad \forall g \in A \setminus \{a\}: P_D^{\text{new}}[a, g] \succ_D P_D^{\text{old}}[a, g].$$

Proof of claim #3:

Suppose $g \in A \setminus \{a\}$. Suppose

$$(4.3.13) \quad \mathfrak{T}(g) := (\{a\} \cup \{ h \in A \setminus \{a\} \mid P_D^{\text{old}}[h,a] >_D P_D^{\text{old}}[a,g] \}).$$

With (4.3.3) and (4.3.13), we get

$$(4.3.14) \quad g \notin \mathfrak{T}(g) \text{ and } a \in \mathfrak{T}(g)$$

and, therefore, $\emptyset \neq \mathfrak{T}(g) \subsetneq A$. Furthermore, we get

$$(4.3.15) \quad \forall i \notin \mathfrak{T}(g) \forall j \in \mathfrak{T}(g): (N^{\text{old}}[i,j], N^{\text{old}}[j,i]) \lesssim_D P_D^{\text{old}}[a,g].$$

Otherwise, there was a path from alternative i to alternative a via alternative j with a strength of more than $P_D^{\text{old}}[a,g]$. But (as $i \notin \mathfrak{T}(g)$) this would contradict the definition of $\mathfrak{T}(g)$.

With (4.3.5), (4.3.1), and (4.3.13), we get

$$(4.3.16) \quad \forall i \notin \mathfrak{T}(g) \forall j \in \mathfrak{T}(g): j >_w i.$$

With (2.1.1) and (4.3.16), we get

$$(4.3.17) \quad \forall i \notin \mathfrak{T}(g) \forall j \in \mathfrak{T}(g): (N^{\text{new}}[i,j], N^{\text{new}}[j,i]) <_D (N^{\text{old}}[i,j], N^{\text{old}}[j,i]).$$

With (4.3.15) and (4.3.17), we get

$$(4.3.18) \quad \forall i \notin \mathfrak{T}(g) \forall j \in \mathfrak{T}(g): (N^{\text{new}}[i,j], N^{\text{new}}[j,i]) <_D P_D^{\text{old}}[a,g].$$

With (4.3.14) and (4.3.18), we get

$$(4.3.19) \quad P_D^{\text{new}}[g,a] <_D P_D^{\text{old}}[a,g]. \quad \square$$

The proof in section 4.3 has first been published by Schulze (2011a). It immediately attracted attention, because it doesn't only prove that there is a tie-breaking ballot w , it also shows how this tie-breaking ballot w can be calculated in a polynomial runtime. Parkes (2012) pointed to the fact that this proof can also be interpreted as saying that it is possible to calculate a voting strategy in a polynomial runtime. This observation by Parkes has been extended by Gaspers (2012), Menton (2013a, 2013b), J. Müller (2013, 2020), and Hemaspaandra (2016).

Papers on the computational manipulability of the Schulze method have also been written by Reisch (2014) and Schend (2015). Surveys on the complexity of calculating a voting strategy under the Schulze method and under other single-winner election methods have been written by Durand (2015), Baumeister (2016), Conitzer (2016), and Faliszewski (2016).

In example 6 (section 3.6), we have $S = \{a, c\}$.

Suppose, we want to make alternative $a \in S$ become the unique winner by adding a single ballot w . The strongest paths from alternative a to every other alternative $y \in A \setminus \{a\}$, as calculated in section 2.3.1, form the following arborescence:

See also the row “from a ...” and the column “... to every other alternative” in the table on page 97. So with (4.3.4) and the arborescence above, we get $a >_w c$, $c >_w b$ and $c >_w d$.

The strengths of the strongest paths in example 6 are:

	$P_D[*,a]$	$P_D[*,b]$	$P_D[*,c]$	$P_D[*,d]$
$P_D[a,*]$	---	(14,9)	(15,8)	(15,8)
$P_D[b,*]$	(12,11)	---	(12,11)	(12,11)
$P_D[c,*]$	(15,8)	(14,9)	---	(16,7)
$P_D[d,*]$	(15,8)	(14,9)	(15,8)	---

So (4.3.5) implies $c >_w b$ and $d >_w b$.

Therefore, we can add the ballot $acdb$ to make alternative a become the unique winner.

Suppose, we want to make alternative $c \in \mathcal{S}$ become the unique winner by adding a single ballot w . The strongest paths from alternative c to every other alternative $y \in A \setminus \{c\}$, as calculated in section 2.3.1, form the following arborescence:

See also the row “from c ...” and the column “... to every other alternative” in the table on page 97. So with (4.3.4) and the arborescence above, we get $c >_w b$, $c >_w d$ and $d >_w a$.

The strengths of the strongest paths in example 6 are:

	$P_D[*,a]$	$P_D[*,b]$	$P_D[*,c]$	$P_D[*,d]$
$P_D[a,*]$	---	(14,9)	(15,8)	(15,8)
$P_D[b,*]$	(12,11)	---	(12,11)	(12,11)
$P_D[c,*]$	(15,8)	(14,9)	---	(16,7)
$P_D[d,*]$	(15,8)	(14,9)	(15,8)	---

So (4.3.5) implies $a >_w b$ and $d >_w b$.

Therefore, we can add the ballot $cdab$ to make alternative c become the unique winner.

4.4. Pareto

The *Pareto criterion* says that the election method must respect unanimous opinions. There are two different versions of the Pareto criterion. The first version addresses situations with “ $a \succ_v b$ for all $v \in V$ ”, while the second version addresses situations with “ $a \succeq_v b$ for all $v \in V$ ” (for some pair of alternatives $a, b \in A$). The first version says that, when every voter strictly prefers alternative a to alternative b (i.e. $a \succ_v b$ for all $v \in V$), then alternative a must perform better than alternative b . The second version says that, when no voter strictly prefers alternative b to alternative a (i.e. $a \succeq_v b$ for all $v \in V$), then alternative b must not perform better than alternative a . We will prove that the Schulze method, as defined in section 2.2, satisfies both versions of the Pareto criterion.

4.4.1. Formulation #1

Definition:

An election method satisfies the first version of the *Pareto criterion* if the following holds:

Suppose:

$$(4.4.1.1) \quad \forall v \in V: a \succ_v b.$$

Then:

$$(4.4.1.2) \quad ab \in O.$$

$$(4.4.1.3) \quad \forall f \in A \setminus \{a, b\}: bf \in O \Rightarrow af \in O.$$

$$(4.4.1.4) \quad \forall f \in A \setminus \{a, b\}: fa \in O \Rightarrow fb \in O.$$

$$(4.4.1.5) \quad b \notin S.$$

Claim:

If $\succ_D$ satisfies (2.1.1), then the Schulze method, as defined in section 2.2, satisfies the first version of the Pareto criterion.

Proof:

With (2.1.1) and (4.4.1.1), we get

$$(4.4.1.6) \quad \forall e, f \in A: (N[a, b], N[b, a]) \succeq_D (N[e, f], N[f, e]).$$

$$(4.4.1.7) \quad [(N[a, b], N[b, a]) \approx_D (N[e, f], N[f, e])] \Leftrightarrow [\forall v \in V: e \succ_v f].$$

With (2.2.4), we get: $ab \in O$, unless the link ab is in a directed cycle that consists of links of which each is at least as strong as the link ab .

However, as we presumed that the individual ballots $\succ_v$ are strict weak orders, it is not possible that there is a directed cycle of unanimous opinions. Therefore, it is not possible that the link ab is in a directed cycle that consists of links of which each is at least as strong as the link ab . Therefore, with (2.2.4), (4.4.1.6), and (4.4.1.7), we get (4.4.1.2). With (4.4.1.2), we get (4.4.1.5). With (4.4.1.2) and the transitivity of O , we get (4.4.1.3) and (4.4.1.4). $\square$

4.4.2. Formulation #2

Definition:

An election method satisfies the second version of the *Pareto criterion* if the following holds:

Suppose:

$$(4.4.2.1) \quad \forall v \in V: a \succ_v b.$$

Then:

$$(4.4.2.2) \quad ba \notin O.$$

$$(4.4.2.3) \quad \forall f \in A \setminus \{a, b\}: bf \in O \Rightarrow af \in O.$$

$$(4.4.2.4) \quad \forall f \in A \setminus \{a, b\}: fa \in O \Rightarrow fb \in O.$$

$$(4.4.2.5) \quad b \in S \Rightarrow a \in S.$$

Claim:

If $\succ_D$ satisfies (2.1.1), then the Schulze method, as defined in section 2.2, satisfies the second version of the Pareto criterion.

Remark:

As O isn't necessarily negatively transitive, (4.4.2.3) and (4.4.2.4) don't follow directly from (4.4.2.2).

Proof:

With (4.4.2.1), we get

$$(4.4.2.6) \quad \forall e \in A \setminus \{a, b\}: N[a, e] \geq N[b, e].$$

With (4.4.2.1), we get

$$(4.4.2.7) \quad \forall e \in A \setminus \{a, b\}: N[e, b] \geq N[e, a].$$

With (2.1.1), (4.4.2.6), and (4.4.2.7), we get

$$(4.4.2.8) \quad \forall e \in A \setminus \{a, b\}: (N[a, e], N[e, a]) \succeq_D (N[b, e], N[e, b]).$$

With (2.1.1), (4.4.2.6), and (4.4.2.7), we get

$$(4.4.2.9) \quad \forall e \in A \setminus \{a, b\}: (N[e, b], N[b, e]) \succeq_D (N[e, a], N[a, e]).$$

Suppose $c(1), \dots, c(n) \in A$ is the strongest path from alternative b to alternative a . With (4.4.2.8) and (4.4.2.9), we get: $a, c(2), \dots, c(n-1), b$ is a path from alternative a to alternative b with at least the same strength. Therefore

$$(4.4.2.10) \quad P_D[a, b] \succeq_D P_D[b, a].$$

With (4.4.2.10), we get (4.4.2.2).

Suppose $c(1), \dots, c(n) \in A$ is the strongest path from alternative b to alternative $f \in A \setminus \{a, b\}$. With (4.4.2.8), we get: $a, c(m+1), \dots, c(n)$, where $c(m)$

is the last occurrence of an alternative of the set $\{a,b\}$, is a path from alternative a to alternative f with at least the same strength. Therefore

$$(4.4.2.11) \quad \forall f \in A \setminus \{a,b\}: P_D[a,f] \approx_D P_D[b,f].$$

Suppose $c(1), \dots, c(n) \in A$ is the strongest path from alternative $f \in A \setminus \{a,b\}$ to alternative a . With (4.4.2.9), we get: $c(1), \dots, c(m-1), b$, where $c(m)$ is the first occurrence of an alternative of the set $\{a,b\}$, is a path from alternative f to alternative b with at least the same strength. Therefore

$$(4.4.2.12) \quad \forall f \in A \setminus \{a,b\}: P_D[f,b] \approx_D P_D[f,a].$$

Part 1: Suppose $f \in A \setminus \{a,b\}$. Suppose

$$(4.4.2.13a) \quad bf \in O.$$

With (4.4.2.13a), we get

$$(4.4.2.14a) \quad P_D[b,f] >_D P_D[f,b].$$

With (4.4.2.11), (4.4.2.14a), and (4.4.2.12), we get

$$(4.4.2.15a) \quad P_D[a,f] \approx_D P_D[b,f] >_D P_D[f,b] \approx_D P_D[f,a].$$

With (4.4.2.15a), we get (4.4.2.3).

Part 2: Suppose $f \in A \setminus \{a,b\}$. Suppose

$$(4.4.2.13b) \quad fa \in O.$$

With (4.4.2.13b), we get

$$(4.4.2.14b) \quad P_D[f,a] >_D P_D[a,f].$$

With (4.4.2.12), (4.4.2.14b), and (4.4.2.11), we get

$$(4.4.2.15b) \quad P_D[f,b] \approx_D P_D[f,a] >_D P_D[a,f] \approx_D P_D[b,f].$$

With (4.4.2.15b), we get (4.4.2.4).

Part 3: Suppose

$$(4.4.2.13c) \quad b \in \mathcal{S}.$$

With (4.4.2.13c), we get

$$(4.4.2.14c) \quad \forall f \in A \setminus \{b\}: fb \notin O.$$

With (4.4.2.4) and (4.4.2.14c), we get

$$(4.4.2.15c) \quad \forall f \in A \setminus \{a,b\}: fa \notin O.$$

With (4.4.2.2) and (4.4.2.15c), we get

$$(4.4.2.16c) \quad \forall f \in A \setminus \{a\}: fa \notin O.$$

With (4.4.2.16c), we get (4.4.2.5). □

Suppose $\succ_D$ satisfies (2.1.1). Then the more detailed definition for the Schulze method, as given in section 5.1, also satisfies the following version of the Pareto criterion:

Suppose:

$$(4.4.2.17) \quad \forall v \in V: a \succ_v b.$$

$$(4.4.2.18) \quad \exists v \in V: a \succ_v b.$$

Then:

$$(4.4.2.19) \quad ab \in O.$$

$$(4.4.2.20) \quad \forall f \in A \setminus \{a, b\}: bf \in O \Rightarrow af \in O.$$

$$(4.4.2.21) \quad \forall f \in A \setminus \{a, b\}: fa \in O \Rightarrow fb \in O.$$

$$(4.4.2.22) \quad b \notin S.$$

4.5. Reversal Symmetry

Reversal symmetry as a criterion for single-winner election methods has been proposed by Saari (1994). This criterion says that, when $\succ_v$ is reversed for all $v \in V$, then also the result of the elections must be reversed; see (4.5.2). S^{old} must not be a strict subset of S^{new} ; S^{new} must not be a strict subset of S^{old} ; see (4.5.3). It should not be possible that the same alternatives are elected in the original situation and in the reversed situation, unless all alternatives are tied; see (4.5.4).

Basic idea of this criterion is that, when there is a vote on the best alternatives and then there is a vote on the worst alternatives and when in both cases the same alternatives are chosen, then this questions the logic of the underlying heuristic of the used election method.

Definition:

An election method satisfies *reversal symmetry* if the following holds:

Suppose:

$$(4.5.1) \quad \forall e, f \in A \forall v \in V: e \succ_v^{\text{old}} f \Leftrightarrow f \succ_v^{\text{new}} e.$$

Then:

$$(4.5.2) \quad \forall a, b \in A: ab \in O^{\text{old}} \Leftrightarrow ba \in O^{\text{new}}.$$

$$(4.5.3) \quad (\exists i \in A: i \in S^{\text{old}} \wedge i \notin S^{\text{new}}) \Leftrightarrow (\exists j \in A: j \notin S^{\text{old}} \wedge j \in S^{\text{new}}).$$

$$(4.5.4) \quad S^{\text{old}} = S^{\text{new}} \Leftrightarrow S^{\text{old}} = A.$$

Claim:

The Schulze method, as defined in section 2.2, satisfies reversal symmetry.

Proof:

With (4.5.1), we get

$$(4.5.5) \quad \forall e, f \in A: N^{\text{old}}[e, f] = N^{\text{new}}[f, e].$$

With (4.5.5), we get

$$(4.5.6) \quad \forall e, f \in A: (N^{\text{old}}[e, f], N^{\text{old}}[f, e]) \approx_D (N^{\text{new}}[f, e], N^{\text{new}}[e, f]).$$

With (4.5.6), we get: When $c(1), \dots, c(n) \in A$ was a path from alternative $g \in A$ to alternative $h \in A \setminus \{g\}$, then $c(n), \dots, c(1)$ is a path from alternative h to alternative g with the same strength. Therefore

$$(4.5.7) \quad \forall g, h \in A: P_D^{\text{old}}[g, h] \approx_D P_D^{\text{new}}[h, g].$$

With (4.5.7), we get (4.5.2).

Part 1:

We now prove: $(\exists i \in A: i \in S^{\text{old}} \wedge i \notin S^{\text{new}}) \Rightarrow (\exists j \in A: j \notin S^{\text{old}} \wedge j \in S^{\text{new}})$.

Suppose $\exists i \in A: i \in S^{\text{old}}$ and $i \notin S^{\text{new}}$. With $i \notin S^{\text{new}}$ and (4.1.14), we get that there is a $j \in S^{\text{new}}$ with $ji \in O^{\text{new}}$. With (4.5.2), we get $ij \in O^{\text{old}}$ and, therefore, $j \notin S^{\text{old}}$. With $j \notin S^{\text{old}}$ and $j \in S^{\text{new}}$, we get the " $\Rightarrow$ " direction of (4.5.3). The proof for the " $\Leftarrow$ " direction of (4.5.3) is analogous.

Part 2:

We now prove: $S^{\text{old}} = A \Rightarrow S^{\text{old}} = S^{\text{new}}$.

Suppose $S^{\text{old}} = A$. Then we get $O^{\text{old}} = \emptyset$. Otherwise, if there was an $ij \in O^{\text{old}}$, we would immediately get $j \notin S^{\text{old}}$ and, therefore, $S^{\text{old}} \neq A$. With $O^{\text{old}} = \emptyset$ and (4.5.2), we get $O^{\text{new}} = \emptyset$ and, therefore, $S^{\text{new}} = A$. With $S^{\text{old}} = A$ and $S^{\text{new}} = A$, we get $S^{\text{old}} = S^{\text{new}}$.

Part 3:

We now prove: $S^{\text{old}} \neq A \Rightarrow S^{\text{old}} \neq S^{\text{new}}$.

Suppose $S^{\text{old}} \neq A$. Then there was a $j \notin S^{\text{old}}$. With (4.1.14), we get that there was an $i \in S^{\text{old}}$ with $ij \in O^{\text{old}}$. With (4.5.2), we get $ji \in O^{\text{new}}$ and, therefore, $i \notin S^{\text{new}}$. With $i \in S^{\text{old}}$ and $i \notin S^{\text{new}}$, we get $S^{\text{old}} \neq S^{\text{new}}$. With part 2 and part 3, we get (4.5.4). $\square$

4.6. Monotonicity and Strict Monotonicity

4.6.1. Monotonicity

Monotonicity says that, when some voters rank alternative $a \in A$ higher [see (4.6.1.1) and (4.6.1.2)] without changing the order in which they rank the other alternatives relatively to each other [see (4.6.1.3)], then this must not hurt alternative a [see (4.6.1.4) – (4.6.1.5)]. Monotonicity is also known as *non-negative responsiveness* and *mono-raise*.

Definition:

An election method satisfies *monotonicity* if the following holds:

Suppose $a \in A$. Suppose the ballots are modified in such a manner that the following three statements are satisfied:

$$(4.6.1.1) \quad \forall f \in A \setminus \{a\} \quad \forall v \in V: a >_v^{\text{old}} f \Rightarrow a >_v^{\text{new}} f.$$

$$(4.6.1.2) \quad \forall f \in A \setminus \{a\} \quad \forall v \in V: a \gtrsim_v^{\text{old}} f \Rightarrow a \gtrsim_v^{\text{new}} f.$$

$$(4.6.1.3) \quad \forall e, f \in A \setminus \{a\} \quad \forall v \in V: e >_v^{\text{old}} f \Leftrightarrow e >_v^{\text{new}} f.$$

Then:

$$(4.6.1.4) \quad \forall b \in A \setminus \{a\}: ab \in O^{\text{old}} \Rightarrow ab \in O^{\text{new}}.$$

$$(4.6.1.5) \quad \forall b \in A \setminus \{a\}: ba \notin O^{\text{old}} \Rightarrow ba \notin O^{\text{new}}.$$

$$(4.6.1.6) \quad S^{\text{old}} = \{a\} \Rightarrow S^{\text{new}} = \{a\}.$$

$$(4.6.1.7) \quad a \in S^{\text{old}} \Rightarrow a \in S^{\text{new}}.$$

Claim:

If $>_D$ satisfies (2.1.1), then the Schulze method, as defined in section 2.2, satisfies monotonicity.

Proof:

With (4.6.1.1), we get

$$(4.6.1.8) \quad \forall f \in A \setminus \{a\}: N^{\text{old}}[a, f] \leq N^{\text{new}}[a, f].$$

With (4.6.1.2), we get

$$(4.6.1.9) \quad \forall f \in A \setminus \{a\}: N^{\text{old}}[f, a] \geq N^{\text{new}}[f, a].$$

With (4.6.1.3), we get

$$(4.6.1.10) \quad \forall e, f \in A \setminus \{a\}: N^{\text{old}}[e, f] = N^{\text{new}}[e, f].$$

With (2.1.1), (4.6.1.8), and (4.6.1.9), we get

$$(4.6.1.11) \quad \forall f \in A \setminus \{a\}: (N^{\text{old}}[a, f], N^{\text{old}}[f, a]) \preceq_D (N^{\text{new}}[a, f], N^{\text{new}}[f, a]).$$

With (2.1.1), (4.6.1.8), and (4.6.1.9), we get

$$(4.6.1.12) \quad \forall f \in A \setminus \{a\}: (N^{\text{old}}[f, a], N^{\text{old}}[a, f]) \succeq_D (N^{\text{new}}[f, a], N^{\text{new}}[a, f]).$$

With (4.6.1.10), we get

$$(4.6.1.13) \quad \forall e, f \in A \setminus \{a\}: (N^{\text{old}}[e, f], N^{\text{old}}[f, e]) \approx_D (N^{\text{new}}[e, f], N^{\text{new}}[f, e]).$$

Suppose $c(1), \dots, c(n) \in A$ was the strongest path from alternative a to alternative $b \in A \setminus \{a\}$. Then with (4.6.1.11) and (4.6.1.13), we get: $c(1), \dots, c(n)$ is a path from alternative a to alternative b with at least the same strength. Therefore

$$(4.6.1.14) \quad \forall b \in A \setminus \{a\}: P_D^{\text{new}}[a, b] \succeq_D P_D^{\text{old}}[a, b].$$

Suppose $c(1), \dots, c(n) \in A$ is the strongest path from alternative $b \in A \setminus \{a\}$ to alternative a . Then with (4.6.1.12) and (4.6.1.13), we get: $c(1), \dots, c(n)$ was a path from alternative b to alternative a with at least the same strength. Therefore

$$(4.6.1.15) \quad \forall b \in A \setminus \{a\}: P_D^{\text{old}}[b, a] \succeq_D P_D^{\text{new}}[b, a].$$

With (4.6.1.14) and (4.6.1.15), we get (4.6.1.4) and (4.6.1.5).

With (4.6.1.4), we get (4.6.1.6).

With (4.6.1.5), we get (4.6.1.7). □

4.6.2. Strict Monotonicity

Definition:

An election method satisfies *strict monotonicity* if the following holds:

Suppose $a \in A$. Suppose the ballots are modified in such a manner that (4.6.1.1) – (4.6.1.3) are satisfied.

Then:

$$(4.6.2.1) \quad a \in \mathcal{S}^{\text{old}} \Rightarrow a \in \mathcal{S}^{\text{new}} \subseteq \mathcal{S}^{\text{old}}.$$

Claim:

If $>_D$ satisfies (2.1.1), then the Schulze method, as defined in section 2.2, satisfies strict monotonicity.

Proof:

“ $a \in \mathcal{S}^{\text{old}} \Rightarrow a \in \mathcal{S}^{\text{new}}$ ” has already been proven in section 4.6.1.

To prove “ $\mathcal{S}^{\text{new}} \subseteq \mathcal{S}^{\text{old}}$ ”, we have to prove: $h \notin \mathcal{S}^{\text{old}} \Rightarrow h \notin \mathcal{S}^{\text{new}}$.

As $a \in \mathcal{S}^{\text{old}}$, we get

$$(4.6.2.2) \quad \forall b \in A \setminus \{a\}: P_D^{\text{old}}[a,b] \approx_D P_D^{\text{old}}[b,a].$$

Suppose $h \notin \mathcal{S}^{\text{old}}$. Then, according to (4.1.14), there must have been an alternative $g \in \mathcal{S}^{\text{old}}$ with

$$(4.6.2.3) \quad P_D^{\text{old}}[g,h] >_D P_D^{\text{old}}[h,g].$$

With (4.6.1.11) – (4.6.1.13) and (4.6.2.3), we get: $P_D^{\text{new}}[g,h] >_D P_D^{\text{new}}[h,g]$, unless at least one of the following two cases occurred.

Case 1: xa was a weakest link in the strongest path from alternative g to alternative h .

Case 2: ay was the unique weakest link in the strongest path from alternative h to alternative g .

With (4.6.2.2), we get: $P_D^{\text{old}}[a,h] \approx_D P_D^{\text{old}}[h,a]$. For $P_D^{\text{old}}[a,h] >_D P_D^{\text{old}}[h,a]$, we would, with (4.6.1.4), immediately get $P_D^{\text{new}}[a,h] >_D P_D^{\text{new}}[h,a]$, so that alternative h is still not a potential winner. Therefore, without loss of generality, we can presume $g \in \mathcal{S}^{\text{old}} \setminus \{a\}$ and

$$(4.6.2.4) \quad P_D^{\text{old}}[a,h] \approx_D P_D^{\text{old}}[h,a].$$

With $a \in \mathcal{S}^{\text{old}}$ and $g \in \mathcal{S}^{\text{old}} \setminus \{a\}$, we get

$$(4.6.2.5) \quad P_D^{\text{old}}[a, g] \approx_D P_D^{\text{old}}[g, a].$$

With (2.2.5), we get

$$(4.6.2.6) \quad \min_D \{ P_D^{\text{old}}[g, h], P_D^{\text{old}}[h, a] \} \lesssim_D P_D^{\text{old}}[g, a].$$

$$(4.6.2.7) \quad \min_D \{ P_D^{\text{old}}[h, a], P_D^{\text{old}}[a, g] \} \lesssim_D P_D^{\text{old}}[h, g].$$

Case 1: Suppose xa was a weakest link in the strongest path from alternative g to alternative h . Then

$$(4.6.2.8a) \quad P_D^{\text{old}}[g, h] \approx_D P_D^{\text{old}}[g, a] \text{ and}$$

$$(4.6.2.9a) \quad P_D^{\text{old}}[a, h] \gtrsim_D P_D^{\text{old}}[g, h].$$

Now (4.6.2.5), (4.6.2.8a), and (4.6.2.3) give

$$(4.6.2.10a) \quad P_D^{\text{old}}[a, g] \approx_D P_D^{\text{old}}[g, a] \approx_D P_D^{\text{old}}[g, h] \succ_D P_D^{\text{old}}[h, g],$$

while (4.6.2.4), (4.6.2.9a), and (4.6.2.3) give

$$(4.6.2.11a) \quad P_D^{\text{old}}[h, a] \approx_D P_D^{\text{old}}[a, h] \gtrsim_D P_D^{\text{old}}[g, h] \succ_D P_D^{\text{old}}[h, g].$$

But (4.6.2.10a) and (4.6.2.11a) together contradict (4.6.2.7).

Case 2: Suppose ay was the unique weakest link in the strongest path from alternative h to alternative g . Then

$$(4.6.2.8b) \quad P_D^{\text{old}}[h, g] \approx_D P_D^{\text{old}}[a, g] \text{ and}$$

$$(4.6.2.9b) \quad P_D^{\text{old}}[h, a] \succ_D P_D^{\text{old}}[h, g].$$

Now (4.6.2.9b), (4.6.2.8b), and (4.6.2.5) give

$$(4.6.2.10b) \quad P_D^{\text{old}}[h, a] \succ_D P_D^{\text{old}}[h, g] \approx_D P_D^{\text{old}}[a, g] \approx_D P_D^{\text{old}}[g, a],$$

while (4.6.2.3), (4.6.2.8b), and (4.6.2.5) give

$$(4.6.2.11b) \quad P_D^{\text{old}}[g, h] \succ_D P_D^{\text{old}}[h, g] \approx_D P_D^{\text{old}}[a, g] \approx_D P_D^{\text{old}}[g, a].$$

But (4.6.2.10b) and (4.6.2.11b) together contradict (4.6.2.6).

We have proven that neither case 1 nor case 2 is possible. Therefore

$$(4.6.2.12) \quad P_D^{\text{new}}[g, h] \succ_D P_D^{\text{new}}[h, g].$$

With (4.6.2.12), we get: $h \notin \mathcal{S}^{\text{new}}$. □

4.7. Independence of Clones

Independence of clones as a criterion for single-winner election methods has been proposed by Tideman (1987) and Zavist (1989). This criterion says that running a large number of similar alternatives, so-called *clones*, must not have any impact on the result of the elections.

The precise definition for a *set of clones* stipulates that every voter ranks all the alternatives of this set in a consecutive manner; see (4.7.1) and (4.7.2). Replacing an alternative $d \in A^{\text{old}}$ by a set of clones K should not change the winner; see (4.7.7) and (4.7.8).

This criterion is very desirable especially for referendums because, while it might be difficult to find several candidates who are simultaneously sufficiently popular to campaign with them and sufficiently similar to misuse them for this strategy, it is usually very simple to formulate a large number of almost identical proposals. For example: In 1969, when the Canadian city that is now known as *Thunder Bay* was amalgamating, there was some controversy over what the name should be. In opinion polls, a majority of the voters preferred the name *The Lakehead* to the name *Thunder Bay*. But when the polls opened, there were three names on the referendum ballot: *Thunder Bay*, *Lakehead*, and *The Lakehead*. As the ballots were counted using *plurality voting*, it was not a surprise when *Thunder Bay* won. The votes were as follows: *Thunder Bay* 15870, *Lakehead* 15302, *The Lakehead* 8377 (www136).

In recent years, cloning strategies are also tried in elections. A good example was the 2019 Ukrainian presidential election. The president of Ukraine is elected by top-two runoff. To split the votes of candidate Yulia Volodymyrivna Tymoshenko (Юлія Володимирівна Тимошénко), her opponents nominated another candidate with almost identical name: Yuri Volodymyrovych Tymoshenko (Юрій Володимирович Тимошénко). The idea was to mislead the supporters of Yulia Tymoshenko so that sufficiently many of them mistakenly vote for the wrong Tymoshenko so that Yulia Tymoshenko doesn't get into the runoff. In the end, Yulia Tymoshenko got 13.40% of the votes in the first round, while Yuri Tymoshenko got 0.62% of the votes. Volodymyr Zelenskyy (30.24%) and Petro Poroshenko (15.95%) got into the runoff. So this cloning strategy had no impact in this election.

An example for a successful cloning strategy in an election was the 2020 election to the State Senate in Florida. To split the votes of incumbent José Javier Rodríguez of State Senate District 37, a candidate with almost identical name was nominated: Alex Rodríguez. In this case, the strategy worked. José Javier Rodríguez (48.51%) lost his seat to Ileana Garcia (48.53%), while Alex Rodríguez got 2.96% of the votes.

The 2021 election to the Legislative Assembly of Saint Petersburg in Russia showed an even more extreme example of a cloning strategy in an election. To keep Boris Vishnevsky (Борис Вишне́вский) of District 2 from winning, his opponents searched for people who could be used as doppelgängers of Boris Vishnevsky. When they had found some, they took the two most suitable of them and adjusted their appearances so that they looked as much as possible like the original Boris Vishnevsky; these

doppelgänger even thinned their hair and grew beards and mustaches similar to the one of the original Boris Vishnevsky. These doppelgänger also legally changed their names to “Boris Vishnevsky” before they submitted their candidacies. So (among other candidates), there were three identical looking candidates with the same name “Boris Vishnevsky” on the ballot. In this case, the cloning strategy had no impact on the result of the election: The original Boris Vishnevsky received 11,062 votes. The two fake candidates received 608 and 510 votes. However, Alexander Rzhanenkov (Александр Ржаненков) of the ruling “United Russia” party won the seat with 12,412 votes.

When this cloning strategy is used, then candidates like Yuri Tymoshenko or Alex Rodríguez or the new Boris Vishnevskies are called *ghost candidates* or *shadow candidates* as they don’t appear in public and don’t campaign.

Definition:

An election method is *independent of clones* if the following holds:

Suppose $d \in A^{\text{old}}$. Suppose $A^{\text{new}} := (A^{\text{old}} \cup K) \setminus \{d\}$.

Suppose alternative d is replaced by the set of alternatives K in such a manner that the following three statements are satisfied:

$$(4.7.1) \quad \forall e \in A^{\text{old}} \setminus \{d\} \forall g \in K \forall v \in V: e >_v^{\text{old}} d \Leftrightarrow e >_v^{\text{new}} g.$$

$$(4.7.2) \quad \forall f \in A^{\text{old}} \setminus \{d\} \forall g \in K \forall v \in V: d >_v^{\text{old}} f \Leftrightarrow g >_v^{\text{new}} f.$$

$$(4.7.3) \quad \forall e, f \in A^{\text{old}} \setminus \{d\} \forall v \in V: e >_v^{\text{old}} f \Leftrightarrow e >_v^{\text{new}} f.$$

Then the following statements are satisfied:

$$(4.7.4) \quad \forall a \in A^{\text{old}} \setminus \{d\} \forall g \in K: ad \in \mathcal{O}^{\text{old}} \Leftrightarrow ag \in \mathcal{O}^{\text{new}}.$$

$$(4.7.5) \quad \forall b \in A^{\text{old}} \setminus \{d\} \forall g \in K: db \in \mathcal{O}^{\text{old}} \Leftrightarrow gb \in \mathcal{O}^{\text{new}}.$$

$$(4.7.6) \quad \forall a, b \in A^{\text{old}} \setminus \{d\}: ab \in \mathcal{O}^{\text{old}} \Leftrightarrow ab \in \mathcal{O}^{\text{new}}.$$

$$(4.7.7) \quad d \in \mathcal{S}^{\text{old}} \Leftrightarrow (\mathcal{S}^{\text{new}} \cap K) \neq \emptyset.$$

$$(4.7.8) \quad \forall a \in A^{\text{old}} \setminus \{d\}: a \in \mathcal{S}^{\text{old}} \Leftrightarrow a \in \mathcal{S}^{\text{new}}.$$

$$(4.7.9) \quad \forall g, h \in K: gh \in \mathcal{O}_K \Leftrightarrow gh \in \mathcal{O}^{\text{new}}.$$

$$(4.7.10) \quad d \in \mathcal{S}^{\text{old}} \Leftrightarrow (\mathcal{S}^{\text{new}} \cap \mathcal{S}_K) \neq \emptyset.$$

$$(4.7.11) \quad \forall g \in K: (\{d\} = \mathcal{S}^{\text{old}} \wedge g \in \mathcal{S}_K) \Rightarrow g \in \mathcal{S}^{\text{new}}.$$

$$(4.7.12) \quad \forall g \in K: (d \in \mathcal{S}^{\text{old}} \wedge \{g\} = \mathcal{S}_K) \Rightarrow g \in \mathcal{S}^{\text{new}}.$$

$$(4.7.13) \quad \forall g \in K: (d \notin \mathcal{S}^{\text{old}} \vee g \notin \mathcal{S}_K) \Rightarrow g \notin \mathcal{S}^{\text{new}}.$$

Claim:

The Schulze method, as defined in section 2.2, satisfies (4.7.4) – (4.7.8). The more detailed definition for the Schulze method, as given in section 5.1, also satisfies (4.7.9) – (4.7.13).

Proof:

We will only prove that the Schulze method, as defined in section 2.2, satisfies (4.7.4) – (4.7.8). The proof that the Schulze method, as defined in section 5.1, also satisfies (4.7.9) – (4.7.13) will then be straight forward.

With (4.7.1), we get

$$(4.7.14) \quad \forall e \in A^{\text{old}} \setminus \{d\} \forall g \in K: N^{\text{old}}[e, d] = N^{\text{new}}[e, g].$$

With (4.7.2), we get

$$(4.7.15) \quad \forall f \in A^{\text{old}} \setminus \{d\} \forall g \in K: N^{\text{old}}[d, f] = N^{\text{new}}[g, f].$$

With (4.7.3), we get

$$(4.7.16) \quad \forall e, f \in A^{\text{old}} \setminus \{d\}: N^{\text{old}}[e, f] = N^{\text{new}}[e, f].$$

With (4.7.14) and (4.7.15), we get

$$(4.7.17) \quad \forall e \in A^{\text{old}} \setminus \{d\} \forall g \in K: \\ (N^{\text{old}}[e, d], N^{\text{old}}[d, e]) \approx_D (N^{\text{new}}[e, g], N^{\text{new}}[g, e]).$$

With (4.7.14) and (4.7.15), we get

$$(4.7.18) \quad \forall f \in A^{\text{old}} \setminus \{d\} \forall g \in K: \\ (N^{\text{old}}[d, f], N^{\text{old}}[f, d]) \approx_D (N^{\text{new}}[g, f], N^{\text{new}}[f, g]).$$

With (4.7.16), we get

$$(4.7.19) \quad \forall e, f \in A^{\text{old}} \setminus \{d\}: (N^{\text{old}}[e, f], N^{\text{old}}[f, e]) \approx_D (N^{\text{new}}[e, f], N^{\text{new}}[f, e]).$$

Suppose $c(1), \dots, c(n) \in A^{\text{old}}$ was the strongest path from alternative $a \in A^{\text{old}} \setminus \{d\}$ to alternative d . Then with (4.7.17) and (4.7.19), we get: $c(1), \dots, c(n-1), g$ is a path from alternative a to alternative $g \in K$ with the same strength. Therefore

$$(4.7.20) \quad \forall a \in A^{\text{old}} \setminus \{d\} \forall g \in K: P_D^{\text{new}}[a, g] \approx_D P_D^{\text{old}}[a, d].$$

Suppose $c(1), \dots, c(n) \in A^{\text{new}}$ is the strongest path from alternative $a \in A^{\text{new}} \setminus K$ to alternative $g \in K$. Then with (4.7.17) and (4.7.19), we get: $c(1), \dots, c(m-1), d$, where $c(m)$ is the first occurrence of an alternative of the set K , was a path from alternative a to alternative d with at least the same strength. Therefore

$$(4.7.21) \quad \forall a \in A^{\text{new}} \setminus K \forall g \in K: P_D^{\text{old}}[a, d] \approx_D P_D^{\text{new}}[a, g].$$

Suppose $c(1), \dots, c(n) \in A^{\text{old}}$ was the strongest path from alternative d to alternative $b \in A^{\text{old}} \setminus \{d\}$. Then with (4.7.18) and (4.7.20), we get: $g, c(2), \dots, c(n)$ is a path from alternative $g \in K$ to alternative b with the same strength. Therefore

$$(4.7.22) \quad \forall b \in A^{\text{old}} \setminus \{d\} \forall g \in K: P_D^{\text{new}}[g, b] \approx_D P_D^{\text{old}}[d, b].$$

Suppose $c(1), \dots, c(n) \in A^{\text{new}}$ is the strongest path from alternative $g \in K$ to alternative $b \in A^{\text{new}} \setminus K$. Then with (4.7.18) and (4.7.19), we get: $d, c(m+1), \dots, c(n)$, where $c(m)$ is the last occurrence of an alternative of the set K , was a path from alternative d to alternative b with at least the same strength. Therefore

$$(4.7.23) \quad \forall b \in A^{\text{new}} \setminus K \forall g \in K: P_D^{\text{old}}[d, b] \approx_D P_D^{\text{new}}[g, b].$$

(α) Suppose the strongest path $c(1), \dots, c(n) \in A^{\text{old}}$ from alternative $a \in A^{\text{old}} \setminus \{d\}$ to alternative $b \in A^{\text{old}} \setminus \{a, d\}$ did not contain alternative d . Then with (4.7.19), we get: $c(1), \dots, c(n)$ is still a path from alternative a to alternative b with the same strength. Therefore: $P_D^{\text{new}}[a, b] \approx_D P_D^{\text{old}}[a, b]$.

(β) Suppose the strongest path $c(1), \dots, c(n) \in A^{\text{old}}$ from alternative $a \in A^{\text{old}} \setminus \{d\}$ to alternative $b \in A^{\text{old}} \setminus \{a, d\}$ contained alternative d . Then with (4.7.17), (4.7.18), and (4.7.19), we get: $c(1), \dots, c(n)$, with alternative d replaced by an arbitrarily chosen alternative $g \in K$, is still a path from alternative a to alternative b with the same strength. Therefore: $P_D^{\text{new}}[a, b] \approx_D P_D^{\text{old}}[a, b]$.

With (α) and (β), we get

$$(4.7.24) \quad \forall a, b \in A^{\text{old}} \setminus \{d\}: P_D^{\text{new}}[a, b] \approx_D P_D^{\text{old}}[a, b].$$

(γ) Suppose the strongest path $c(1), \dots, c(n) \in A^{\text{new}}$ from alternative $a \in A^{\text{new}} \setminus K$ to alternative $b \in A^{\text{new}} \setminus (K \cup \{a\})$ does not contain alternatives of the set K . Then with (4.7.19), we get: $c(1), \dots, c(n)$ was a path from alternative a to alternative b with the same strength. Therefore: $P_D^{\text{old}}[a, b] \approx_D P_D^{\text{new}}[a, b]$.

(δ) Suppose the strongest path $c(1), \dots, c(n) \in A^{\text{new}}$ from alternative $a \in A^{\text{new}} \setminus K$ to alternative $b \in A^{\text{new}} \setminus (K \cup \{a\})$ contains some alternatives of the set K . Then with (4.7.17), (4.7.18), and (4.7.19), we get: $c(1), \dots, c(s-1), d, c(t+1), \dots, c(n)$, where $c(s)$ is the first occurrence of an alternative of the set K and $c(t)$ is the last occurrence of an alternative of the set K , was a path from alternative a to alternative b with at least the same strength. Therefore: $P_D^{\text{old}}[a, b] \approx_D P_D^{\text{new}}[a, b]$.

With (γ) and (δ), we get

$$(4.7.25) \quad \forall a, b \in A^{\text{new}} \setminus K: P_D^{\text{old}}[a, b] \approx_D P_D^{\text{new}}[a, b].$$

Combining (4.7.20) and (4.7.21) gives

$$(4.7.26) \quad \forall a \in A^{\text{old}} \setminus \{d\} \forall g \in K: P_D^{\text{old}}[a, d] \approx_D P_D^{\text{new}}[a, g].$$

Combining (4.7.22) and (4.7.23) gives

$$(4.7.27) \quad \forall b \in A^{\text{old}} \setminus \{d\} \forall g \in K: P_D^{\text{old}}[d, b] \approx_D P_D^{\text{new}}[g, b].$$

Combining (4.7.24) and (4.7.25) gives

$$(4.7.28) \quad \forall a, b \in A^{\text{old}} \setminus \{d\}: P_D^{\text{old}}[a, b] \approx_D P_D^{\text{new}}[a, b].$$

With (4.7.26) – (4.7.28), we get (4.7.4) – (4.7.6).

Part 1:

Suppose $d \in S^{\text{old}}$. Then

$$(4.7.29) \quad \forall a \in A^{\text{old}} \setminus \{d\}: ad \notin O^{\text{old}}.$$

With (4.7.4) and (4.7.29), we get

$$(4.7.30) \quad \forall a \in A^{\text{new}} \setminus K \forall g \in K: ag \notin O^{\text{new}}.$$

Since the binary relation O^{new} , as defined in (2.2.1), is asymmetric and transitive, there must be an alternative $k \in K$ with

$$(4.7.31) \quad \forall l \in K \setminus \{k\}: lk \notin O^{\text{new}}.$$

With (4.7.30) and (4.7.31), we get $k \in (S^{\text{new}} \cap K)$ and, therefore, $(S^{\text{new}} \cap K) \neq \emptyset$.

Part 2:

Suppose $d \notin S^{\text{old}}$. Then

$$(4.7.32) \quad \exists a \in A^{\text{old}} \setminus \{d\}: ad \in O^{\text{old}}.$$

With (4.7.4) and (4.7.32), we get

$$(4.7.33) \quad \exists a \in A^{\text{new}} \setminus K \forall g \in K: ag \in O^{\text{new}}.$$

With (4.7.33), we get: $(S^{\text{new}} \cap K) = \emptyset$.

With part 1 and part 2, we get (4.7.7).

Part 3:

Suppose $a \in A^{\text{old}} \setminus \{d\}$ and $a \in S^{\text{old}}$. Then

$$(4.7.34) \quad da \notin O^{\text{old}}.$$

$$(4.7.35) \quad \forall b \in A^{\text{old}} \setminus \{a, d\}: ba \notin O^{\text{old}}.$$

With (4.7.26), (4.7.27) and (4.7.34), we get

$$(4.7.36) \quad \forall g \in K: ga \notin O^{\text{new}}.$$

With (4.7.28) and (4.7.35), we get

$$(4.7.37) \quad \forall b \in A^{\text{new}} \setminus (K \cup \{a\}): ba \notin O^{\text{new}}.$$

With (4.7.36) and (4.7.37), we get: $a \in S^{\text{new}}$.

Part 4:

Suppose $a \in A^{\text{old}} \setminus \{d\}$ and $a \notin \mathcal{S}^{\text{old}}$. Then at least one of the following two statements must have been valid:

$$(4.7.38a) \quad da \in \mathcal{O}^{\text{old}}.$$

$$(4.7.38b) \quad \exists b \in A^{\text{old}} \setminus \{a, d\}: ba \in \mathcal{O}^{\text{old}}.$$

With (4.7.26), (4.7.27), (4.7.28), and (4.7.38), we get that at least one of the following two statements must be valid:

$$(4.7.39a) \quad \forall g \in K: ga \in \mathcal{O}^{\text{new}}.$$

$$(4.7.39b) \quad \exists b \in A^{\text{new}} \setminus (K \cup \{a\}): ba \in \mathcal{O}^{\text{new}}.$$

With (4.7.39), we get: $a \notin \mathcal{S}^{\text{new}}$.

With part 3 and part 4, we get (4.7.8). □

Section 4.7 is also discussed by Camps (2008, 2012b), Bouremel (2017a, 2017b), and Zedam (2018). On the other side, Felsenthal (2011, page 28, footnote 6; 2018, page 20, footnote 2; 2019, page 10, footnote 2) explicitly refuses to discuss the Schulze method because of the fact that it is independent of clones.

4.8. Smith Criterion, Condorcet Winners, Condorcet Losers

The *Smith set* is the smallest set $\emptyset \neq B \subseteq A$ with

$$(4.8.1) \quad \forall a \in B \forall b \notin B: N[a,b] > N[b,a].$$

The *Smith criterion* and *Smith-IIA* (where IIA means “independence of irrelevant alternatives”) say that *weak* alternatives should have no impact on the result of the elections.

Suppose:

$$(4.8.2) \quad \emptyset \neq B_1 \subsetneq A, \emptyset \neq B_2 \subsetneq A, B_1 \cup B_2 = A, B_1 \cap B_2 = \emptyset.$$

$$(4.8.3) \quad \forall a \in B_1 \forall b \in B_2: N[a,b] > N[b,a].$$

Then a *weak* alternative in the Smith paradigm is an alternative $b \in B_2$. Adding or removing a weak alternative $b \in B_2$ should have no impact on the set S of potential winners.

Definition:

An election method satisfies the *Smith criterion* if the following holds:

Suppose (4.8.2) and (4.8.3). Then:

$$(4.8.4) \quad \forall a \in B_1 \forall b \in B_2: ab \in O.$$

$$(4.8.5) \quad \emptyset \neq S \subseteq B_1.$$

Remark:

If B_1 consists of only one alternative $a \in A$, then this alternative is the so-called *Condorcet winner* and the Smith criterion becomes the so-called *Condorcet criterion* or *Condorcet winner criterion* (Condorcet, 1785). In short:

$$(4.8.6) \quad \text{Alternative } a \in A \text{ is a Condorcet winner : } \Leftrightarrow N[a,b] > N[b,a] \text{ for all } b \in A \setminus \{a\}.$$

$$(4.8.7) \quad \text{An election method satisfies the Condorcet criterion if the following holds:}$$

$$(i) \quad \text{Alternative } a \in A \text{ is a Condorcet winner. } \Rightarrow S = \{a\}.$$

$$(ii) \quad \text{Alternative } a \in A \text{ is a Condorcet winner.} \\ \Rightarrow \forall b \in A \setminus \{a\}: ab \in O.$$

If B_2 consists of only one alternative $b \in A$, then this alternative is the so-called *Condorcet loser* and the Smith criterion becomes the so-called *Condorcet loser criterion*. In short:

$$(4.8.8) \quad \text{Alternative } b \in A \text{ is a Condorcet loser : } \Leftrightarrow N[a,b] > N[b,a] \text{ for all } a \in A \setminus \{b\}.$$

(4.8.9) An election method satisfies the *Condorcet loser criterion* if the following holds:

- (i) Alternative $b \in A$ is a Condorcet loser. $\Rightarrow b \notin S$.
- (ii) Alternative $b \in A$ is a Condorcet loser.
 $\Rightarrow \forall a \in A \setminus \{b\}: ab \in O$.

Claim:

If $>_D$ satisfies (2.1.5), then the Schulze method, as defined in section 2.2, satisfies the Smith criterion.

Proof:

The proof is trivial. Presumption (2.1.5) guarantees that any pairwise victory is stronger than any pairwise defeat. If $a \in B_1$ and $b \in B_2$, then already the link ab is a path from alternative a to alternative b that consists only of a pairwise victory. On the other side, (4.8.3) says that there cannot be a path from alternative b to alternative a that contains no pairwise defeat. So already the link ab is stronger than any path from alternative b to alternative a . $\square$

Definition:

An election method satisfies *Smith-IIA* if the following holds:

Suppose (4.8.2) and (4.8.3). Then:

(4.8.10) If $d \in B_2$ is removed, then

$$(a) \quad \forall e, f \in B_1: ef \in O^{\text{old}} \Leftrightarrow ef \in O^{\text{new}}.$$

$$(b) \quad S^{\text{old}} = S^{\text{new}}.$$

(4.8.11) If $d \in B_1$ is removed, then

$$\forall e, f \in B_2: ef \in O^{\text{old}} \Leftrightarrow ef \in O^{\text{new}}.$$

Claim:

If $\succ_D$ satisfies (2.1.5), then the Schulze method, as defined in section 2.2, satisfies Smith-IIA.

Proof:

We will prove (4.8.10)(a). The proof for (4.8.11) is analogous.

(4.8.10)(b) follows directly from (4.8.5) and (4.8.10)(a).

Part 1: Suppose $ef \in B_1$. Suppose $ef \in O^{\text{old}}$. Then

$$(4.8.12) \quad P_D^{\text{old}}[ef] \succ_D P_D^{\text{old}}[fe].$$

With (2.2.3), we get

$$(4.8.13) \quad P_D^{\text{old}}[ef] \approx_D (N[ef], N[fe]).$$

With (4.8.12) and (2.2.3), we get

$$(4.8.14) \quad P_D^{\text{old}}[ef] \succ_D P_D^{\text{old}}[fe] \approx_D (N[fe], N[ef]).$$

With (4.8.13) and (4.8.14), we get

$$(4.8.15) \quad P_D^{\text{old}}[ef] \approx_D \max_D \{ (N[ef], N[fe]), (N[fe], N[ef]) \}.$$

With (4.8.3), we get: Any path from alternative $e \in B_1$ to alternative $f \in B_1$ that contained alternative $d \in B_2$ necessarily contained a pairwise defeat.

As it is not possible that the link ef is a pairwise defeat and that simultaneously the link fe is a pairwise defeat, $\max_D \{ (N[ef], N[fe]), (N[fe], N[ef]) \}$ is stronger than any pairwise defeat [because of (2.1.5)]. Therefore, with (4.8.3) and (4.8.15), we get: The strongest path from alternative $e \in B_1$ to alternative $f \in B_1$ did not contain alternative $d \in B_2$. Therefore

$$(4.8.16) \quad P_D^{\text{new}}[ef] \approx_D P_D^{\text{old}}[ef].$$

As the elimination of alternative $d \in B_2$ only removes paths, we get

$$(4.8.17) \quad P_D^{\text{new}}[fe] \approx_D P_D^{\text{old}}[fe].$$

With (4.8.16), (4.8.12), and (4.8.17), we get

$$(4.8.18) \quad P_D^{\text{new}}[ef] \approx_D P_D^{\text{old}}[ef] \succ_D P_D^{\text{old}}[fe] \approx_D P_D^{\text{new}}[fe].$$

With (4.8.18), we get: $ef \in O^{\text{new}}$.

Part 2: The proof for “ $P_D^{\text{old}} [f,e] >_D P_D^{\text{old}} [e,f]$ ” is analogous.

Part 3: When we have $P_D^{\text{old}} [e,f] \approx_D P_D^{\text{old}} [f,e]$ then, with the same argumentation as in Part 1, we get

$$(4.8.19) \quad P_D^{\text{old}} [e,f] \approx_D \max_D \{ (N[e,f], N[f,e]), (N[f,e], N[e,f]) \}.$$

$$(4.8.20) \quad P_D^{\text{old}} [f,e] \approx_D \max_D \{ (N[e,f], N[f,e]), (N[f,e], N[e,f]) \}.$$

So with the same argumentation as in Part 1, we can show that neither the strongest path from alternative $e \in B_1$ to alternative $f \in B_1$ nor the strongest path from alternative $f \in B_1$ to alternative $e \in B_1$ did contain alternative $d \in B_2$. $\square$

The *majority criterion for solid coalitions* says that, when a majority of the voters strictly prefers every alternative of a given set of alternatives to every alternative outside this set of alternatives, then the winner must be chosen from this set. In short, an election method satisfies the *majority criterion for solid coalitions* if the following holds:

$$\begin{array}{ll} \text{Suppose} & (4.8.2). \\ \text{Suppose} & \parallel \{ v \in V \mid \forall a \in B_1 \forall b \in B_2: a >_v b \} \parallel > N/2. \\ \text{Then} & S \subseteq B_1. \end{array}$$

If B_1 consists of only one alternative $a \in A$, then this is the so-called *majority criterion* or *majority winner criterion*. If B_2 consists of only one alternative $b \in A$, then this is the so-called *majority loser criterion*.

The Smith criterion implies the majority criterion for solid coalitions, the Condorcet criterion, and the Condorcet loser criterion. The majority criterion for solid coalitions implies the majority criterion and the majority loser criterion. The Condorcet criterion implies the majority criterion. The Condorcet loser criterion implies the majority loser criterion.

Participation says that adding a list W of ballots, on which every alternative of set B_1 (with $\emptyset \neq B_1 \subsetneq A$) is strictly preferred to every alternative of set B_2 (with $B_2 := A \setminus B_1$), must not change the winner from an alternative of set B_1 to an alternative of set B_2 . In short, an election method satisfies *participation* if the following holds:

Suppose (4.8.2).

Suppose (4.8.21) $\forall a \in B_1 \forall b \in B_2 \forall w \in W: a \succ_w b.$

Suppose (4.8.22) $V^{\text{new}} := V^{\text{old}} + W.$

Then (4.8.23) $\forall e \in B_1 \forall f \in B_2: ef \in O^{\text{old}} \Rightarrow ef \in O^{\text{new}}.$

(4.8.24) $\forall e \in B_1 \forall f \in B_2: fe \notin O^{\text{old}} \Rightarrow fe \notin O^{\text{new}}.$

(4.8.25) $(S^{\text{old}} \cap B_1) \neq \emptyset \Rightarrow (S^{\text{new}} \cap B_1) \neq \emptyset.$

(4.8.26) $(S^{\text{old}} \cap B_2) = \emptyset \Rightarrow (S^{\text{new}} \cap B_2) = \emptyset.$

Unfortunately, the Condorcet criterion is incompatible with the participation criterion (Moulin, 1988). Example 7 (section 3.7) shows a drastic violation of the participation criterion.

While the Condorcet criterion and the participation criterion are incompatible, random simulations by Xia (2021a, fig. 13(b) and 14(b)) showed that, of all Condorcet-consistent methods, the Schulze method violates the participation criterion the least frequently.

Relationships between the criteria defined in sections 4.8 and 4.11

4.9. MinMax Set

For all $\emptyset \neq B \subsetneq A$, we define

$$(4.9.1) \quad \Gamma_D(B) := \max_D \{ (N[x,y], N[y,x]) \mid x \notin B, y \in B \}.$$

In short: $\Gamma_D(B)$ is the strongest defeat of an alternative in B by an alternative from outside of B .

Furthermore, we define

$$(4.9.2) \quad \beta_D := \min_D \{ \Gamma_D(B) \mid \emptyset \neq B \subsetneq A \}.$$

$$(4.9.3) \quad \mathfrak{B}_D := \cup \{ \emptyset \neq B \subsetneq A \mid \Gamma_D(B) \approx_D \beta_D \}.$$

$\mathfrak{B}_D$ is the *MinMax set*. $\mathfrak{B}_D$ has the following properties:

1. $\mathfrak{B}_D \neq \emptyset$.
2. If $\mathfrak{B}_D$ consists of only one alternative $a \in A$, then alternative a is the unique Simpson-Kramer MinMax winner (i.e. that alternative $a \in A$ with minimum $\max_D \{ (N[b,a], N[a,b]) \mid b \in A \setminus \{a\} \}$).
3. If $d \in \mathfrak{B}_D$ is replaced by a set of alternatives K as described in (4.7.1) – (4.7.3), then $\mathfrak{B}_D^{\text{new}} = (\mathfrak{B}_D \cup K) \setminus \{d\}$.
4. If $d \notin \mathfrak{B}_D$ is replaced by a set of alternatives K as described in (4.7.1) – (4.7.3), then $\mathfrak{B}_D^{\text{new}} = \mathfrak{B}_D$.

So, in some sense, the MinMax set $\mathfrak{B}_D$ is a cloneproof generalization of the Simpson-Kramer MinMax winner.

When we want primarily that the used election method is independent of clones and secondarily that the strongest link ef , that is overruled when determining the winner, is minimized, then we have to demand that the winner is always chosen from the MinMax set $\mathfrak{B}_D$.

Claim:

The Schulze method, as defined in section 2.2, has the following properties:

$$(4.9.4) \quad \forall a \in \mathfrak{B}_D \forall b \notin \mathfrak{B}_D: ab \in \mathcal{O}.$$

$$(4.9.5) \quad \mathcal{S} \subseteq \mathfrak{B}_D.$$

Proof:

Suppose $a \in \mathfrak{B}_D$. Then, with (4.9.3), we get

$$(4.9.6) \quad \exists \emptyset \neq B \subsetneq A: \Gamma_D(B) \approx_D \beta_D \text{ and } a \in B.$$

Suppose $b \notin \mathfrak{B}_D$. Then, with (4.9.3), we get

$$(4.9.7) \quad \gamma_D := \min_D \{ \Gamma_D(B) \mid \emptyset \neq B \subsetneq A \text{ and } b \in B \} \succ_D \beta_D.$$

We will prove the following claims:

Claim #1: $P_D[b, a] \precsim_D \beta_D$.

Claim #2: $P_D[a, b] \succeq_D \gamma_D$.

With claim #1, claim #2 and (4.9.7), we get

$$(4.9.8) \quad P_D[a, b] \succeq_D \gamma_D \succ_D \beta_D \succeq_D P_D[b, a].$$

With (4.9.8), we get (4.9.4). With (4.9.4), we get (4.9.5).

Proof of claim #1:

With (4.9.6) and (4.9.7), we get

$$(4.9.9) \quad \exists \emptyset \neq B \subsetneq A: \Gamma_D(B) \approx_D \beta_D \text{ and } a \in B \text{ and } b \notin B.$$

Suppose $c(1), \dots, c(n) \in A$ is the strongest path from alternative b to alternative a . Suppose $c(i)$ is the last alternative with $c(i) \notin B$. Then we get $(N[c(i), c(i+1)], N[c(i+1), c(i)]) \precsim_D \beta_D$. Therefore, we get

$$(4.9.10) \quad P_D[b, a] \precsim_D \beta_D.$$

Proof of claim #2:

We can construct a path from alternative a to alternative b with a strength of at least γ_D as follows:

- (1) We start with $E_1 := \{a\}$ and $i := 1$. Trivially, we get $b \notin E_1$ and $P_D[a, h] \succeq_D \gamma_D$ for all $h \in E_1 \setminus \{a\}$.
- (2) At each stage, we consider the set $B_i := A \setminus E_i$.

With $b \in B_i$ and with (4.9.7), we get

$$(4.9.11) \quad \Gamma_D(B_i) \approx_D \max_D \{ (N[x, y], N[y, x]) \mid x \notin B_i, y \in B_i \} \succeq_D \gamma_D.$$

We choose $f \in E_i$ and $g \in B_i$ with

$$(4.9.12) \quad (N[f, g], N[g, f]) \approx_D \max_D \{ (N[x, y], N[y, x]) \mid x \notin B_i, y \in B_i \} \succeq_D \gamma_D.$$

We define $E_{i+1} := E_i \cup \{g\}$.

With $f \in E_i$, with $P_D[a, h] \succeq_D \gamma_D$ for all $h \in E_i \setminus \{a\}$, with $(N[f, g], N[g, f]) \succeq_D \gamma_D$, and with $E_{i+1} := E_i \cup \{g\}$, we get

$$(4.9.13) \quad P_D[a, h] \succeq_D \gamma_D \text{ for all } h \in E_{i+1} \setminus \{a\}.$$

- (3) We repeat stage 2 with $i \rightarrow i+1$, until $g \equiv b$.

Therefore, we get

$$(4.9.14) \quad P_D[a, b] \succeq_D \gamma_D. \quad \square$$

Example 8 (section 3.8) shows that IPDA and the desideratum, that the winner is always chosen from the MinMax set $\mathfrak{B}_D$, are incompatible. In example 8(old), we get $\mathfrak{B}_D^{\text{old}} = \{a, c, d\}$. In example 8(new), we get $\mathfrak{B}_D^{\text{new}} = \{b\}$. Therefore, $(\mathfrak{B}_D^{\text{old}} \cap \mathfrak{B}_D^{\text{new}}) = \emptyset$. Thus, the desideratum, that the winner is always chosen from the MinMax set $\mathfrak{B}_D$, implies that the winner must change.

Actually, the Schulze method can be described completely with the desideratum to find a binary relation $\mathcal{O}$ on A that, primarily, is independent of clones (as defined in section 4.7) and that, secondarily, tries to rank the alternatives according to their worst defeats.

For all $a, b \in A$, we define

$$(4.9.15) \quad \gamma_D[a, b] := \min_D \{ \Gamma_D(B) \mid \emptyset \neq B \subsetneq A \text{ and } a \notin B \text{ and } b \in B \}.$$

$$(4.9.16) \quad ab \in \mathcal{O} : \Leftrightarrow \gamma_D[a, b] >_D \gamma_D[b, a].$$

To prove that (4.9.16) is identical to (2.2.1), we have to prove $\gamma_D[a, b] = P_D[a, b]$. This proof is identical to the proof for (4.9.4).

Example 1

With $\Gamma_D(B) := \max_D \{ (N[x,y], N[y,x]) \mid x \notin B, y \in B \}$,
we get in example 1 (section 3.1):

$$\begin{aligned} \Gamma_D(\{a\}) &= (N[b,a], N[a,b]) = (13, 8). \\ \Gamma_D(\{b\}) &= (N[d,b], N[b,d]) = (19, 2). \\ \Gamma_D(\{c\}) &= (N[a,c], N[c,a]) = (14, 7). \\ \Gamma_D(\{d\}) &= (N[c,d], N[d,c]) = (12, 9). \\ \Gamma_D(\{a,b\}) &= (N[d,b], N[b,d]) = (19, 2). \\ \Gamma_D(\{a,c\}) &= (N[b,a], N[a,b]) = (13, 8). \\ \Gamma_D(\{a,d\}) &= (N[b,a], N[a,b]) = (13, 8). \\ \Gamma_D(\{b,c\}) &= (N[d,b], N[b,d]) = (19, 2). \\ \Gamma_D(\{b,d\}) &= (N[c,b], N[b,c]) = (15, 6). \\ \Gamma_D(\{c,d\}) &= (N[a,c], N[c,a]) = (14, 7). \\ \Gamma_D(\{a,b,c\}) &= (N[d,b], N[b,d]) = (19, 2). \\ \Gamma_D(\{a,b,d\}) &= (N[c,b], N[b,c]) = (15, 6). \\ \Gamma_D(\{a,c,d\}) &= (N[b,a], N[a,b]) = (13, 8). \\ \Gamma_D(\{b,c,d\}) &= (N[a,c], N[c,a]) = (14, 7). \end{aligned}$$

With $\beta_D := \min_D \{ \Gamma_D(B) \mid \emptyset \neq B \subsetneq A \}$, we get: $\beta_D = (12, 9)$.

With $\mathfrak{B}_D := \bigcup \{ \emptyset \neq B \subsetneq A \mid \Gamma_D(B) \approx_D \beta_D \}$, we get $\mathfrak{B}_D = \{d\}$.

So with (4.9.5), we get $\mathcal{S} = \{d\}$.

With $\gamma_D[x,y] := \min_D \{ \Gamma_D(B) \mid \emptyset \neq B \subsetneq A \text{ and } x \notin B \text{ and } y \in B \}$, we get:

$$\begin{aligned} \gamma_D[a,b] &= \Gamma_D(\{b,c,d\}) = (14, 7). \\ \gamma_D[a,c] &= \Gamma_D(\{c\}) = \Gamma_D(\{c,d\}) = \Gamma_D(\{b,c,d\}) = (14, 7). \\ \gamma_D[a,d] &= \Gamma_D(\{d\}) = (12, 9). \\ \gamma_D[b,a] &= \Gamma_D(\{a\}) = \Gamma_D(\{a,c\}) = \Gamma_D(\{a,d\}) = \Gamma_D(\{a,c,d\}) = (13, 8). \\ \gamma_D[b,c] &= \Gamma_D(\{a,c\}) = \Gamma_D(\{a,c,d\}) = (13, 8). \\ \gamma_D[b,d] &= \Gamma_D(\{d\}) = (12, 9). \\ \gamma_D[c,a] &= \Gamma_D(\{a\}) = \Gamma_D(\{a,d\}) = (13, 8). \\ \gamma_D[c,b] &= \Gamma_D(\{b,d\}) = \Gamma_D(\{a,b,d\}) = (15, 6). \\ \gamma_D[c,d] &= \Gamma_D(\{d\}) = (12, 9). \\ \gamma_D[d,a] &= \Gamma_D(\{a\}) = \Gamma_D(\{a,c\}) = (13, 8). \\ \gamma_D[d,b] &= \Gamma_D(\{b\}) = \Gamma_D(\{a,b\}) = \Gamma_D(\{b,c\}) = \Gamma_D(\{a,b,c\}) = (19, 2). \\ \gamma_D[d,c] &= \Gamma_D(\{a,c\}) = (13, 8). \end{aligned}$$

Example 2

With $\Gamma_D(B) := \max_D \{ (N[x,y], N[y,x]) \mid x \notin B, y \in B \}$,
we get in example 2 (section 3.2):

$$\begin{aligned} \Gamma_D(\{a\}) &= (N[d,a], N[a,d]) = (18, 12). \\ \Gamma_D(\{b\}) &= (N[d,b], N[b,d]) = (21, 9). \\ \Gamma_D(\{c\}) &= (N[b,c], N[c,b]) = (19, 11). \\ \Gamma_D(\{d\}) &= (N[c,d], N[d,c]) = (20, 10). \\ \Gamma_D(\{a,b\}) &= (N[d,b], N[b,d]) = (21, 9). \\ \Gamma_D(\{a,c\}) &= (N[b,c], N[c,b]) = (19, 11). \\ \Gamma_D(\{a,d\}) &= (N[c,d], N[d,c]) = (20, 10). \\ \Gamma_D(\{b,c\}) &= (N[d,b], N[b,d]) = (21, 9). \\ \Gamma_D(\{b,d\}) &= (N[c,d], N[d,c]) = (20, 10). \\ \Gamma_D(\{c,d\}) &= (N[b,c], N[c,b]) = (19, 11). \\ \Gamma_D(\{a,b,c\}) &= (N[d,b], N[b,d]) = (21, 9). \\ \Gamma_D(\{a,b,d\}) &= (N[c,d], N[d,c]) = (20, 10). \\ \Gamma_D(\{a,c,d\}) &= (N[b,c], N[c,b]) = (19, 11). \\ \Gamma_D(\{b,c,d\}) &= (N[a,c], N[c,a]) = (17, 13). \end{aligned}$$

With $\beta_D := \min_D \{ \Gamma_D(B) \mid \emptyset \neq B \subsetneq A \}$, we get: $\beta_D = (17, 13)$.

With $\mathfrak{B}_D := \bigcup \{ \emptyset \neq B \subsetneq A \mid \Gamma_D(B) \approx_D \beta_D \}$, we get $\mathfrak{B}_D = \{b, c, d\}$.

So with (4.9.5), we get $\mathcal{S} \subseteq \{b, c, d\}$.

With $\gamma_D[x,y] := \min_D \{ \Gamma_D(B) \mid \emptyset \neq B \subsetneq A \text{ and } x \notin B \text{ and } y \in B \}$, we get:

$$\begin{aligned} \gamma_D[a,b] &= \Gamma_D(\{b, c, d\}) = (17, 13). \\ \gamma_D[a,c] &= \Gamma_D(\{b, c, d\}) = (17, 13). \\ \gamma_D[a,d] &= \Gamma_D(\{b, c, d\}) = (17, 13). \\ \gamma_D[b,a] &= \Gamma_D(\{a\}) = (18, 12). \\ \gamma_D[b,c] &= \Gamma_D(\{c\}) = \Gamma_D(\{a, c\}) = \Gamma_D(\{c, d\}) = \Gamma_D(\{a, c, d\}) = (19, 11). \\ \gamma_D[b,d] &= \Gamma_D(\{c, d\}) = \Gamma_D(\{a, c, d\}) = (19, 11). \\ \gamma_D[c,a] &= \Gamma_D(\{a\}) = (18, 12). \\ \gamma_D[c,b] &= \Gamma_D(\{b, d\}) = \Gamma_D(\{a, b, d\}) = (20, 10). \\ \gamma_D[c,d] &= \Gamma_D(\{d\}) = \Gamma_D(\{a, d\}) = \Gamma_D(\{b, d\}) = \Gamma_D(\{a, b, d\}) = (20, 10). \\ \gamma_D[d,a] &= \Gamma_D(\{a\}) = (18, 12). \\ \gamma_D[d,b] &= \Gamma_D(\{b\}) = \Gamma_D(\{a, b\}) = \Gamma_D(\{b, c\}) = \Gamma_D(\{a, b, c\}) = (21, 9). \\ \gamma_D[d,c] &= \Gamma_D(\{c\}) = \Gamma_D(\{a, c\}) = (19, 11). \end{aligned}$$

Example 3

With $\Gamma_D(B) := \max_D \{ (N[x,y], N[y,x]) \mid x \notin B, y \in B \}$,
we get in example 3 (section 3.3):

$$\begin{aligned}
 \Gamma_D(\{a\}) &= (N[b,a], N[a,b]) = (25, 20). \\
 \Gamma_D(\{b\}) &= (N[c,b], N[b,c]) = (29, 16). \\
 \Gamma_D(\{c\}) &= (N[d,c], N[c,d]) = (28, 17). \\
 \Gamma_D(\{d\}) &= (N[b,d], N[d,b]) = (33, 12). \\
 \Gamma_D(\{e\}) &= (N[c,e], N[e,c]) = (24, 21). \\
 \Gamma_D(\{a,b\}) &= (N[c,b], N[b,c]) = (29, 16). \\
 \Gamma_D(\{a,c\}) &= (N[d,c], N[c,d]) = (28, 17). \\
 \Gamma_D(\{a,d\}) &= (N[b,d], N[d,b]) = (33, 12). \\
 \Gamma_D(\{a,e\}) &= (N[b,a], N[a,b]) = (25, 20). \\
 \Gamma_D(\{b,c\}) &= (N[d,c], N[c,d]) = (28, 17). \\
 \Gamma_D(\{b,d\}) &= (N[e,d], N[d,e]) = (31, 14). \\
 \Gamma_D(\{b,e\}) &= (N[c,b], N[b,c]) = (29, 16). \\
 \Gamma_D(\{c,d\}) &= (N[b,d], N[d,b]) = (33, 12). \\
 \Gamma_D(\{c,e\}) &= (N[d,c], N[c,d]) = (28, 17). \\
 \Gamma_D(\{d,e\}) &= (N[b,d], N[d,b]) = (33, 12). \\
 \Gamma_D(\{a,b,c\}) &= (N[d,c], N[c,d]) = (28, 17). \\
 \Gamma_D(\{a,b,d\}) &= (N[e,d], N[d,e]) = (31, 14). \\
 \Gamma_D(\{a,b,e\}) &= (N[c,b], N[b,c]) = (29, 16). \\
 \Gamma_D(\{a,c,d\}) &= (N[b,d], N[d,b]) = (33, 12). \\
 \Gamma_D(\{a,c,e\}) &= (N[d,c], N[c,d]) = (28, 17). \\
 \Gamma_D(\{a,d,e\}) &= (N[b,d], N[d,b]) = (33, 12). \\
 \Gamma_D(\{b,c,d\}) &= (N[e,d], N[d,e]) = (31, 14). \\
 \Gamma_D(\{b,c,e\}) &= (N[d,c], N[c,d]) = (28, 17). \\
 \Gamma_D(\{b,d,e\}) &= (N[a,d], N[d,a]) = (30, 15). \\
 \Gamma_D(\{c,d,e\}) &= (N[b,d], N[d,b]) = (33, 12). \\
 \Gamma_D(\{a,b,c,d\}) &= (N[e,d], N[d,e]) = (31, 14). \\
 \Gamma_D(\{a,b,c,e\}) &= (N[d,c], N[c,d]) = (28, 17). \\
 \Gamma_D(\{a,b,d,e\}) &= (N[c,b], N[b,c]) = (29, 16). \\
 \Gamma_D(\{a,c,d,e\}) &= (N[b,d], N[d,b]) = (33, 12). \\
 \Gamma_D(\{b,c,d,e\}) &= (N[a,d], N[d,a]) = (30, 15).
 \end{aligned}$$

With $\beta_D := \min_D \{ \Gamma_D(B) \mid \emptyset \neq B \subsetneq A \}$, we get: $\beta_D = (24, 21)$.

With $\mathfrak{B}_D := \bigcup \{ \emptyset \neq B \subsetneq A \mid \Gamma_D(B) \approx_D \beta_D \}$, we get $\mathfrak{B}_D = \{e\}$.

So with (4.9.5), we get $\mathcal{S} = \{e\}$.

With $\gamma_D[x,y] := \min_D \{ \Gamma_D(B) \mid \emptyset \neq B \subsetneq A \text{ and } x \notin B \text{ and } y \in B \}$, we get:

$$\gamma_D[a,b] = \Gamma_D(\{b,c\}) = \Gamma_D(\{b,c,e\}) = (28,17).$$

$$\gamma_D[a,c] = \Gamma_D(\{c\}) = \Gamma_D(\{b,c\}) = \Gamma_D(\{c,e\}) = \Gamma_D(\{b,c,e\}) = (28,17).$$

$$\gamma_D[a,d] = \Gamma_D(\{b,d,e\}) = \Gamma_D(\{b,c,d,e\}) = (30,15).$$

$$\gamma_D[a,e] = \Gamma_D(\{e\}) = (24,21).$$

$$\gamma_D[b,a] = \Gamma_D(\{a\}) = \Gamma_D(\{a,e\}) = (25,20).$$

$$\gamma_D[b,c] = \Gamma_D(\{c\}) = \Gamma_D(\{a,c\}) = \Gamma_D(\{c,e\}) = \Gamma_D(\{a,c,e\}) = (28,17).$$

$$\gamma_D[b,d] = \Gamma_D(\{d\}) = \Gamma_D(\{a,d\}) = \Gamma_D(\{c,d\}) = \Gamma_D(\{d,e\}) = \Gamma_D(\{a,c,d\}) = \Gamma_D(\{a,d,e\}) = \Gamma_D(\{c,d,e\}) = \Gamma_D(\{a,c,d,e\}) = (33,12).$$

$$\gamma_D[b,e] = \Gamma_D(\{e\}) = (24,21).$$

$$\gamma_D[c,a] = \Gamma_D(\{a\}) = \Gamma_D(\{a,e\}) = (25,20).$$

$$\gamma_D[c,b] = \Gamma_D(\{b\}) = \Gamma_D(\{a,b\}) = \Gamma_D(\{b,e\}) = \Gamma_D(\{a,b,e\}) = \Gamma_D(\{a,b,d,e\}) = (29,16).$$

$$\gamma_D[c,d] = \Gamma_D(\{a,b,d,e\}) = (29,16).$$

$$\gamma_D[c,e] = \Gamma_D(\{e\}) = (24,21).$$

$$\gamma_D[d,a] = \Gamma_D(\{a\}) = \Gamma_D(\{a,e\}) = (25,20).$$

$$\gamma_D[d,b] = \Gamma_D(\{b,c\}) = \Gamma_D(\{a,b,c\}) = \Gamma_D(\{b,c,e\}) = \Gamma_D(\{a,b,c,e\}) = (28,17).$$

$$\gamma_D[d,c] = \Gamma_D(\{c\}) = \Gamma_D(\{a,c\}) = \Gamma_D(\{b,c\}) = \Gamma_D(\{c,e\}) = \Gamma_D(\{a,b,c\}) = \Gamma_D(\{a,c,e\}) = \Gamma_D(\{b,c,e\}) = \Gamma_D(\{a,b,c,e\}) = (28,17).$$

$$\gamma_D[d,e] = \Gamma_D(\{e\}) = (24,21).$$

$$\gamma_D[e,a] = \Gamma_D(\{a\}) = (25,20).$$

$$\gamma_D[e,b] = \Gamma_D(\{b,c\}) = \Gamma_D(\{a,b,c\}) = (28,17).$$

$$\gamma_D[e,c] = \Gamma_D(\{c\}) = \Gamma_D(\{a,c\}) = \Gamma_D(\{b,c\}) = \Gamma_D(\{a,b,c\}) = (28,17).$$

$$\gamma_D[e,d] = \Gamma_D(\{b,d\}) = \Gamma_D(\{a,b,d\}) = \Gamma_D(\{b,c,d\}) = \Gamma_D(\{a,b,c,d\}) = (31,14).$$

4.10. Prudence

Prudence as a criterion for single-winner election methods has been proposed by Köhler (1978) and generalized by Arrow and Raynaud (1986). *Prudence* says (1) that the collective ranking O should be a strict partial order on A and (2) that the strength λ_D of the strongest link ef , that is not respected by O , should be as weak as possible. So

$$\lambda_D := \max_D \{ (N[ef], N[f,e]) \mid ef \notin O \}$$

should be minimized.

A *directed cycle* is a sequence of alternatives $c(1), \dots, c(n) \in A$ with the following properties:

1. $c(1) \equiv c(n)$.
2. $n \in \mathbb{N}$ with $2 < n \leq (C+1)$.
3. For all $i, j \in \{1, \dots, n\}$: $(i < j \wedge (i, j) \neq (1, n)) \Rightarrow c(i) \in A \setminus \{c(j)\}$.

A *majority cycle* is a directed cycle with the following additional property:

4. For all $i = 1, \dots, (n-1)$: $N[c(i), c(i+1)] > N[c(i+1), c(i)]$.

It is obvious that, when there is a directed cycle $c(1), \dots, c(n)$, then the strongest link, that is not respected by the binary relation O , is at least as strong as the weakest link $c(i), c(i+1)$ of this directed cycle. Therefore, we get:

$$(4.10.1) \quad \lambda_D \succeq_D \min_D \{ (N[c(i), c(i+1)], N[c(i+1), c(i)]) \mid i = 1, \dots, (n-1) \}.$$

As we have to make this consideration for all directed cycles, the maximum, that we can ask for, is the following criterion.

Definition:

Suppose $\lambda_D \in \mathbb{N}_0 \times \mathbb{N}_0$ is the strength of the strongest directed cycle.

$$(4.10.2) \quad \lambda_D := \max_D \{ \min_D \{ (N[c(i), c(i+1)], N[c(i+1), c(i)]) \mid i = 1, \dots, (n-1) \} \mid c(1), \dots, c(n) \text{ is a directed cycle} \}.$$

Then an election method is *prudent* if the following holds:

$$(4.10.3) \quad \forall a, b \in A: (N[a, b], N[b, a]) >_D \lambda_D \Rightarrow ab \in O.$$

$$(4.10.4) \quad \forall a, b \in A: (N[a, b], N[b, a]) >_D \lambda_D \Rightarrow b \notin \mathcal{S}.$$

Claim:

The Schulze method, as defined in section 2.2, is prudent.

Proof:

The proof is trivial. With (2.2.4), we get: $ab \in O$, unless the link ab is in a directed cycle that consists of links of which each is at least as strong as the link ab . $\square$

Example 1

In example 1 (section 3.1), the strongest directed cycle (measured by the strength of its weakest link) is $a,(14,7),c,(15,6),b,(13,8),a$ with a strength of $\lambda_D \approx_D (13,8)$. So prudence says that the collective ranking O must respect all links that are stronger than $(13,8)$.

$$(N[d,b],N[b,d]) = (19,2) >_D (13,8) \approx_D \lambda_D \Rightarrow db \in O.$$

$$(N[c,b],N[b,c]) = (15,6) >_D (13,8) \approx_D \lambda_D \Rightarrow cb \in O.$$

$$(N[a,c],N[c,a]) = (14,7) >_D (13,8) \approx_D \lambda_D \Rightarrow ac \in O.$$

With $db \in O$, $cb \in O$, and $ac \in O$, we get $b \notin S$ and $c \notin S$.

With $ac \in O$ and $cb \in O$ and the transitivity of O , we get $ab \in O$.

Example 2

In example 2 (section 3.2), the strongest directed cycle (measured by the strength of its weakest link) is $b,(19,11),c,(20,10),d,(21,9),b$ with a strength of $\lambda_D \approx_D (19,11)$. So prudence says that the collective ranking O must respect all links that are stronger than $(19,11)$.

$$(N[d,b],N[b,d]) = (21,9) >_D (19,11) \approx_D \lambda_D \Rightarrow db \in O.$$

$$(N[c,d],N[d,c]) = (20,10) >_D (19,11) \approx_D \lambda_D \Rightarrow cd \in O.$$

With $db \in O$ and $cd \in O$, we get $b \notin S$ and $d \notin S$.

With $cd \in O$ and $db \in O$ and the transitivity of O , we get $cb \in O$.

Example 3

In example 3 (section 3.3), the strongest directed cycle (measured by the strength of its weakest link) is $b,(33,12),d,(28,17),c,(29,16),b$ with a strength of $\lambda_D \approx_D (28,17)$. So prudence says that the collective ranking O must respect all links that are stronger than $(28,17)$.

$$(N[b,d],N[d,b]) = (33,12) >_D (28,17) \approx_D \lambda_D \Rightarrow bd \in O.$$

$$(N[e,d],N[d,e]) = (31,14) >_D (28,17) \approx_D \lambda_D \Rightarrow ed \in O.$$

$$(N[a,d],N[d,a]) = (30,15) >_D (28,17) \approx_D \lambda_D \Rightarrow ad \in O.$$

$$(N[c,b],N[b,c]) = (29,16) >_D (28,17) \approx_D \lambda_D \Rightarrow cb \in O.$$

With $bd \in O$, $ed \in O$, $ad \in O$, and $cb \in O$, we get $b \notin S$ and $d \notin S$.

With $cb \in O$ and $bd \in O$ and the transitivity of O , we get $cd \in O$.

4.11. Schwartz

The Schwartz criterion as a criterion for single-winner election methods has been proposed by Schwartz (1986). The Schwartz criterion implies the Smith criterion.

A *chain* from alternative $x \in A$ to alternative $y \in A \setminus \{x\}$ is a sequence of alternatives $c(1), \dots, c(n) \in A$ with the following properties:

1. $x \equiv c(1)$.
2. $y \equiv c(n)$.
3. $n \in \mathbb{N}$ with $2 \leq n \leq C$.
4. For all $i, j \in \{1, \dots, n\}$: $i \neq j \Rightarrow c(i) \in A \setminus \{c(j)\}$.
5. For all $i = 1, \dots, (n-1)$: $N[c(i), c(i+1)] > N[c(i+1), c(i)]$.

Definition:

An election method satisfies the *Schwartz criterion* if the following holds:

Suppose there is a chain from alternative $a \in A$ to alternative $b \in A$ and no chain from alternative b to alternative a . Then:

$$(4.11.1) \quad ab \in O.$$

$$(4.11.2) \quad b \notin S.$$

Claim:

If $>_D$ satisfies (2.1.5), then the Schulze method, as defined in section 2.2, satisfies the Schwartz criterion.

Proof:

The proof is trivial. □

Definition:

The *Schwartz set* $\emptyset \neq B \subseteq A$ is defined as follows:

$$(4.11.3) \quad a \in B : \Leftrightarrow (\forall b \in A \setminus \{a\} : \\ (\text{There is a chain from alternative } b \text{ to alternative } a. \\ \Rightarrow \text{There is a chain from alternative } a \text{ to alternative } b.))$$

A real-life example that illustrates the difference between the Smith set, as defined in (4.8.1), and the Schwartz set, as defined in (4.11.3), was the nomination (on 25/26 February 2011) of the top candidate for the party list of the Pirate Party for the elections (on 18 September 2011) to the Berlin House of Representatives. The Schulze method was used for this nomination. The following digraph shows the result of the nomination (www137):

There were 106 valid ballots in total. There were three majority cycles (as defined in section 4.10): Magalski $\rightarrow$ Baum $\rightarrow$ Mayer $\rightarrow$ Magalski, Delius $\rightarrow$ Weiss $\rightarrow$ Höfinghoff $\rightarrow$ Wittich $\rightarrow$ Delius, and Delius $\rightarrow$ Höfinghoff $\rightarrow$ Wittich $\rightarrow$ Delius. There were two pairwise ties: Magalski $\leftrightarrow$ Wittich and Weiss $\leftrightarrow$ Wittich. The Smith set consists of all 7 candidates, while the Schwartz set contains only 3 candidates (Magalski, Baum, Mayer). The Schulze ranking is Magalski $>_S$ Baum $>_S$ Mayer $>_S$ Delius $>_S$ Weiss $>_S$ Höfinghoff $>_S$ Wittich for $>_{margin}$, $>_{ratio}$, and $>_{win}$ and Magalski $>_S$ Baum $>_S$ Mayer $>_S$ Wittich $>_S$ Delius $>_S$ Weiss $>_S$ Höfinghoff for $>_{los}$.

4.12. Weak Condorcet Winners and Weak Condorcet Losers

4.12.1. Weak Condorcet Winners

A *Condorcet winner* is an alternative $a \in A$ that wins every head-to-head contest with some other alternative $b \in A \setminus \{a\}$. See (4.8.6). In other words:

$$(4.12.1.1) \quad \text{Alternative } a \in A \text{ is a } \textit{Condorcet winner} : \Leftrightarrow \\ N[a,b] > N[b,a] \text{ for all } b \in A \setminus \{a\}.$$

A *weak Condorcet winner* is an alternative $a \in A$ that doesn't lose any head-to-head contest with some other alternative $b \in A \setminus \{a\}$. In other words:

$$(4.12.1.2) \quad \text{Alternative } a \in A \text{ is a } \textit{weak Condorcet winner} : \Leftrightarrow \\ N[a,b] \geq N[b,a] \text{ for all } b \in A \setminus \{a\}.$$

Suppose $\mathcal{E}$ is the set of weak Condorcet winners. Then we get:

$$(4.12.1.3) \quad a \in \mathcal{E} : \Leftrightarrow N[a,b] \geq N[b,a] \text{ for all } b \in A \setminus \{a\}.$$

A frequently stated desideratum says that, when there is a weak Condorcet winner, then it should win.

When there happens to be exactly one potential winner $x \in A$ and exactly one weak Condorcet winner $y \in A$, it is obvious what the above desideratum means: Alternative x and alternative y must be the same alternative.

In other words:

$$(4.12.1.4) \quad (\| \mathcal{E} \| = 1 \text{ and } \| \mathcal{S} \| = 1) \Rightarrow \mathcal{E} = \mathcal{S}.$$

However, when there happens to be more than one potential winner or more than one weak Condorcet winner, the proper formulation for the above desideratum isn't obvious. The most intuitive formulation is:

$$(4.12.1.5) \quad \mathcal{E} \neq \emptyset \Rightarrow \mathcal{S} \subseteq \mathcal{E}.$$

Formulation (4.12.1.5) says that, when there is at least one weak Condorcet winner, then every potential winner should be a weak Condorcet winner. Unfortunately, the following example demonstrates that (4.12.1.5) is incompatible with reversal symmetry:

Suppose there are four alternatives $A = \{a, b, c, d\}$. Suppose $N^{\text{old}}[a, b] = N^{\text{old}}[b, a]$, $N^{\text{old}}[a, c] = N^{\text{old}}[c, a]$, $N^{\text{old}}[a, d] = N^{\text{old}}[d, a]$, $N^{\text{old}}[b, c] > N^{\text{old}}[c, b]$, $N^{\text{old}}[c, d] > N^{\text{old}}[d, c]$, and $N^{\text{old}}[d, b] > N^{\text{old}}[b, d]$. Then we get $\mathcal{E}^{\text{old}} = \{a\}$. With (4.12.1.5) and the requirement that $\mathcal{S}^{\text{old}}$ must not be empty, we get $\mathcal{S}^{\text{old}} = \{a\}$.

When the individual preferences are reversed, as defined in (4.5.1), we get $N^{\text{new}}[a, b] = N^{\text{new}}[b, a]$, $N^{\text{new}}[a, c] = N^{\text{new}}[c, a]$, $N^{\text{new}}[a, d] = N^{\text{new}}[d, a]$, $N^{\text{new}}[b, c] < N^{\text{new}}[c, b]$, $N^{\text{new}}[c, d] < N^{\text{new}}[d, c]$, and $N^{\text{new}}[d, b] < N^{\text{new}}[b, d]$. Therefore, we get $\mathcal{E}^{\text{new}} = \{a\}$. With (4.12.1.5) and the requirement that $\mathcal{S}^{\text{new}}$ must not be empty, we get $\mathcal{S}^{\text{new}} = \{a\}$.

But $\mathcal{S}^{\text{old}} = \{a\}$ and $\mathcal{S}^{\text{new}} = \{a\}$ together contradict (4.5.4).

In short: It can happen that the same alternative is the unique weak Condorcet winner in the original situation and, simultaneously, the unique weak Condorcet winner in the reversed situation. Therefore, (4.12.1.5) cannot be compatible with reversal symmetry.

Furthermore, the following example demonstrates that (4.12.1.5) is incompatible with independence of clones:

Suppose there are only two alternatives $A^{\text{old}} = \{a, b\}$. Suppose $N[a, b] = N[b, a]$. Then we get $\mathcal{E}^{\text{old}} = \{a, b\}$. With (4.12.1.5), we get $\mathcal{S}^{\text{old}} \subseteq \{a, b\}$.

Case I: Suppose $a \in \mathcal{S}^{\text{old}}$. When alternative a is replaced by alternatives a_1, a_2, a_3 such that $N[a_1, a_2] > N[a_2, a_1]$, $N[a_2, a_3] > N[a_3, a_2]$, and $N[a_3, a_1] > N[a_1, a_3]$ and such that (4.7.1) – (4.7.3) are satisfied, we get $\mathcal{E}^{\text{new}} = \{b\}$. With (4.12.1.5) and the requirement that $\mathcal{S}^{\text{new}}$ must not be empty, we get $\mathcal{S}^{\text{new}} = \{b\}$. But with (4.7.7) and $a \in \mathcal{S}^{\text{old}}$, we get $(\mathcal{S}^{\text{new}} \cap \{a_1, a_2, a_3\}) \neq \emptyset$. As $\mathcal{S}^{\text{new}} = \{b\}$ and $(\mathcal{S}^{\text{new}} \cap \{a_1, a_2, a_3\}) \neq \emptyset$ are incompatible, we get $a \notin \mathcal{S}^{\text{old}}$.

Case II: Suppose $b \in \mathcal{S}^{\text{old}}$. When alternative b is replaced by alternatives b_1, b_2, b_3 such that $N[b_1, b_2] > N[b_2, b_1]$, $N[b_2, b_3] > N[b_3, b_2]$, and $N[b_3, b_1] > N[b_1, b_3]$ and such that (4.7.1) – (4.7.3) are satisfied, we get $\mathcal{E}^{\text{new}} = \{a\}$. With (4.12.1.5) and the requirement that $\mathcal{S}^{\text{new}}$ must not be empty, we get $\mathcal{S}^{\text{new}} = \{a\}$. But with (4.7.7) and $b \in \mathcal{S}^{\text{old}}$, we get $(\mathcal{S}^{\text{new}} \cap \{b_1, b_2, b_3\}) \neq \emptyset$. As $\mathcal{S}^{\text{new}} = \{a\}$ and $(\mathcal{S}^{\text{new}} \cap \{b_1, b_2, b_3\}) \neq \emptyset$ are incompatible, we get $b \notin \mathcal{S}^{\text{old}}$.

However, $a \notin \mathcal{S}^{\text{old}}$ and $b \notin \mathcal{S}^{\text{old}}$ together are incompatible with the requirement that $\mathcal{S}^{\text{old}}$ must not be empty.

In short: When a weak Condorcet winner is replaced by a set of clones, as defined in (4.7.1) – (4.7.3), it is not guaranteed that at least one of these clones is a weak Condorcet winner. Therefore, (4.12.1.5) cannot be compatible with independence of clones.

The above examples demonstrate that, to satisfy reversal symmetry and independence of clones, we have, in some situations, to allow alternatives, which are not weak Condorcet winners, to be among the potential winners.

So the maximum, that we could ask for, is:

$$(4.12.1.6) \quad \mathcal{E} \subseteq \mathcal{S}.$$

Formulation (4.12.1.6) says that every weak Condorcet winner should be a potential winner, but it makes no stipulations about those alternatives which are not weak Condorcet winners. In (4.12.1.6), the presumption “ $\mathcal{E} \neq \emptyset$ ” is not needed. We don’t have to write “ $\mathcal{E} \neq \emptyset \Rightarrow \mathcal{E} \subseteq \mathcal{S}$ ” because the empty set is, by definition, subset of every set.

The following proof demonstrates that the Schulze method satisfies (4.12.1.6) and that, therefore, (4.12.1.6) is compatible with reversal symmetry and independence of clones.

Claim:

If $>_D$ satisfies (2.1.4) and (2.1.5), then the Schulze method, as defined in section 2.2, satisfies (4.12.1.6).

Proof:

Step 1:

(2.1.4) says that all ties have equivalent strengths. So without loss of generality, we can set

$$(4.12.1.7) \quad \forall x \in \mathbb{N}_0: (x, x) \approx_D (1, 1).$$

Step 2:

With (2.2.3), we get

$$(4.12.1.8) \quad \forall a \in \mathcal{E} \forall b \in A \setminus \{a\}: P_D[a, b] \approx_D (N[a, b], N[b, a]).$$

With (4.12.1.3), we get

$$(4.12.1.9) \quad \forall a \in \mathcal{E} \forall b \in A \setminus \{a\}: N[a, b] \geq N[b, a].$$

With (2.1.5), (4.12.1.7), and (4.12.1.9), we get

$$(4.12.1.10) \quad \forall a \in \mathcal{E} \forall b \in A \setminus \{a\}: (N[a, b], N[b, a]) \approx_D (1, 1).$$

Step 3:

Suppose $a \in \mathcal{E}$. Suppose $b \in A \setminus \{a\}$. Suppose the link ca is the last link in the strongest path from alternative b to alternative a . Then we get

$$(4.12.1.11) \quad P_D[b, a] \approx_D (N[c, a], N[a, c]).$$

With (4.12.1.9), we get

$$(4.12.1.12) \quad N[a, c] \geq N[c, a].$$

With (2.1.5), (4.12.1.7), and (4.12.1.12), we get

$$(4.12.1.13) \quad (N[c, a], N[a, c]) \approx_D (1, 1).$$

With (4.12.1.8), (4.12.1.10), (4.12.1.13), and (4.12.1.11), we get

$$(4.12.1.14) \quad P_D[a, b] \approx_D (N[a, b], N[b, a]) \approx_D (1, 1) \approx_D (N[c, a], N[a, c]) \approx_D P_D[b, a].$$

The considerations in (4.12.1.11) – (4.12.1.14) can be repeated for every $a \in \mathcal{E}$ and every $b \in A \setminus \{a\}$. Therefore, with (4.12.1.14), we get

$$(4.12.1.15) \quad \forall a \in \mathcal{E} \forall b \in A \setminus \{a\}: P_D[a, b] \approx_D P_D[b, a].$$

With (4.12.1.15), we get

$$(4.12.1.16) \quad a \in \mathcal{E} \Rightarrow a \in \mathcal{S}.$$

With (4.12.1.16), we get (4.12.1.6). □

The following desideratum further reduces the scenarios where some alternative, that is not a weak Condorcet winner, can be a potential winner:

$$(4.12.1.17) \quad \forall a \in \mathcal{E} \forall b \in (\mathcal{S} \setminus \mathcal{E}): N[a,b] = N[b,a].$$

Desideratum (4.12.1.17) says that an alternative, that is not a weak Condorcet winner, can be a potential winner only when it pairwise ties all weak Condorcet winners.

Claim:

If $\succ_D$ satisfies (2.1.5), then the Schulze method, as defined in section 2.2, satisfies (4.12.1.17).

Proof:

Suppose $a \in \mathcal{E}$ and $b \in (\mathcal{S} \setminus \mathcal{E})$.

Step 1:

$N[a,b] < N[b,a]$ is a contradiction to the presumption that alternative a is a weak Condorcet winner.

Step 2:

It remains to be proven that $N[a,b] > N[b,a]$ is not possible.

So suppose

$$(4.12.1.18) \quad N[a,b] > N[b,a].$$

With (2.2.3), we get

$$(4.12.1.19) \quad P_D[a,b] \succeq_D (N[a,b], N[b,a]).$$

Suppose the link ca is the last link in the strongest path from alternative b to alternative a . Then we get

$$(4.12.1.20) \quad P_D[b,a] \preceq_D (N[c,a], N[a,c]).$$

With $a \in \mathcal{E}$ and (4.12.1.3), we get

$$(4.12.1.21) \quad N[a,c] \geq N[c,a].$$

With (2.1.5), (4.12.1.18), and (4.12.1.21), we get

$$(4.12.1.22) \quad (N[a,b], N[b,a]) \succ_D (N[c,a], N[a,c]).$$

With (4.12.1.19), (4.12.1.22), and (4.12.1.20), we get

$$(4.12.1.23) \quad P_D[a,b] \succeq_D (N[a,b], N[b,a]) \succ_D (N[c,a], N[a,c]) \preceq_D P_D[b,a].$$

So alternative a disqualifies alternative b . But this is a contradiction to the presumption that alternative b is a potential winner. $\square$

4.12.2. Weak Condorcet Losers

A *Condorcet loser* is an alternative $b \in A$ that loses every head-to-head contest with some other alternative $a \in A \setminus \{b\}$. See (4.8.8). In other words:

$$(4.12.2.1) \quad \text{Alternative } b \in A \text{ is a } \textit{Condorcet loser} : \Leftrightarrow \\ N[a,b] > N[b,a] \text{ for all } a \in A \setminus \{b\}.$$

A *weak Condorcet loser* is an alternative $b \in A$ that doesn't win any head-to-head contest with some other alternative $a \in A \setminus \{b\}$. In other words:

$$(4.12.2.2) \quad \text{Alternative } b \in A \text{ is a } \textit{weak Condorcet loser} : \Leftrightarrow \\ N[a,b] \geq N[b,a] \text{ for all } a \in A \setminus \{b\}.$$

Suppose $\mathcal{F}$ is the set of weak Condorcet losers. Then we get:

$$(4.12.2.3) \quad b \in \mathcal{F} : \Leftrightarrow N[a,b] \geq N[b,a] \text{ for all } a \in A \setminus \{b\}.$$

A frequently stated desideratum says that a weak Condorcet loser should not be a potential winner. So with (4.12.2.3), we get

$$(4.12.2.4) \quad \forall b \in A: (b \in \mathcal{F} \Rightarrow b \notin \mathcal{S}).$$

However, a problem with desideratum (4.12.2.4) is that it can happen that a weak Condorcet loser is, simultaneously, a weak Condorcet winner. In this case, (4.12.2.4) is incompatible with (4.12.1.6).

Example: Suppose there are only $C = 2$ alternatives $a, b \in A$. Suppose there is a pairwise tie, $N[a, b] = N[b, a]$. Then both alternatives are weak Condorcet losers and, simultaneously, weak Condorcet winners. (4.12.1.6) says: $a \in \mathcal{S}$ and $b \in \mathcal{S}$. (4.12.2.4) says: $a \notin \mathcal{S}$ and $b \notin \mathcal{S}$.

So the maximum, that we could ask for, is:

$$(4.12.2.5) \quad \forall b \in A: ((b \in \mathcal{F} \text{ and } b \notin \mathcal{E}) \Rightarrow b \notin \mathcal{S}).$$

Desideratum (4.12.2.5) says that a weak Condorcet loser should not win, unless it is also a weak Condorcet winner. The following proof demonstrates that the Schulze method satisfies (4.12.2.5) and that, therefore, there is no need to weaken (4.12.2.5) any further.

Claim:

If $>_D$ satisfies (2.1.5), then the Schulze method, as defined in section 2.2, satisfies (4.12.2.5).

Proof:

With (2.2.3), we get

$$(4.12.2.6) \quad \forall a, b \in A: P_D[a, b] \approx_D (N[a, b], N[b, a]).$$

Suppose $b \in \mathcal{F}$ and $b \notin \mathcal{E}$.

With $b \in \mathcal{F}$ and (4.12.2.3), we get

$$(4.12.2.7) \quad \forall a \in A \setminus \{b\}: N[a, b] \geq N[b, a].$$

With $b \notin \mathcal{E}$ and (4.12.1.3), we get

$$(4.12.2.8) \quad \exists a \in A \setminus \{b\}: N[a, b] > N[b, a].$$

For the rest of this proof, we choose an alternative $a \in A \setminus \{b\}$ with (4.12.2.8). Suppose the link bc is the first link in the strongest path from alternative b to alternative a . Then we get

$$(4.12.2.9) \quad P_D[b, a] \approx_D (N[b, c], N[c, b]).$$

With (4.12.2.7), we get

$$(4.12.2.10) \quad N[c, b] \geq N[b, c].$$

With (2.1.5), (4.12.2.8), and (4.12.2.10), we get

$$(4.12.2.11) \quad (N[b, c], N[c, b]) <_D (N[a, b], N[b, a]).$$

With (4.12.2.6), (4.12.2.11), and (4.12.2.9), we get

$$(4.12.2.12) \quad P_D[a, b] \approx_D (N[a, b], N[b, a]) >_D (N[b, c], N[c, b]) \approx_D P_D[b, a].$$

So alternative a disqualifies alternative b . So $b \notin \mathcal{S}$. □

The following desideratum says that a weak Condorcet loser cannot be a unique winner:

$$(4.12.2.13) \quad \forall b \in A: (b \in \mathcal{F} \Rightarrow \mathcal{S} \neq \{b\}).$$

Claim:

If $>_D$ satisfies (2.1.4) and (2.1.5), then the Schulze method, as defined in section 2.2, satisfies (4.12.2.13).

Proof:

Step 1:

(2.1.4) says that all ties have equivalent strengths. So without loss of generality, we can set

$$(4.12.2.14) \quad \forall x \in \mathbb{N}_0: (x, x) \approx_D (1, 1).$$

Step 2:

With (2.2.3), we get

$$(4.12.2.15) \quad \forall a, b \in A: P_D[a, b] \approx_D (N[a, b], N[b, a]).$$

Suppose $b \in \mathcal{F}$. With (4.12.2.3), we get

$$(4.12.2.16) \quad \forall a \in A \setminus \{b\}: N[a, b] \geq N[b, a].$$

With (2.1.5), (4.12.2.14), and (4.12.2.16), we get

$$(4.12.2.17) \quad \forall a \in A \setminus \{b\}: (N[a, b], N[b, a]) \approx_D (1, 1).$$

For the rest of this proof, we choose a concrete alternative $a \in A \setminus \{b\}$. Suppose the link bc is the first link in the strongest path from alternative b to alternative a . Then we get

$$(4.12.2.18) \quad P_D[b,a] \preceq_D (N[b,c], N[c,b]).$$

With (4.12.2.16), we get

$$(4.12.2.19) \quad N[c,b] \geq N[b,c].$$

With (2.1.5), (4.12.2.14), and (4.12.2.19), we get

$$(4.12.2.20) \quad (N[b,c], N[c,b]) \preceq_D (1,1).$$

With (4.12.2.15), (4.12.2.17), (4.12.2.20), and (4.12.2.18), we get

$$(4.12.2.21) \quad P_D[a,b] \preceq_D (N[a,b], N[b,a]) \preceq_D (1,1) \preceq_D (N[b,c], N[c,b]) \preceq_D P_D[b,a].$$

The considerations in (4.12.2.18) – (4.12.2.21) can be repeated for every $a \in A \setminus \{b\}$. Therefore, with (4.12.2.21), we get

$$(4.12.2.22) \quad \forall a \in A \setminus \{b\}: P_D[a,b] \preceq_D P_D[b,a].$$

Step 3:

As O is transitive, there is an alternative d in $A \setminus \{b\}$ that is not disqualified by any other alternative in $A \setminus \{b\}$. We get

$$(4.12.2.23) \quad \exists d \in A \setminus \{b\} \forall e \in A \setminus \{b,d\}: ed \notin O.$$

With (4.12.2.22), we get that alternative b doesn't disqualify alternative d . With (4.12.2.23), we get that no other alternative $e \in A \setminus \{b,d\}$ disqualifies alternative d . Therefore, alternative d is a potential winner. Therefore, we get $d \in S$. Therefore, we get $S \neq \{b\}$. Therefore, we get (4.12.2.13). $\square$

4.13. Increasing Sequential Independence

Increasing sequential independence says that, when alternative $a \in A$ is a winner, then there must be an alternative $d \in A \setminus \{a\}$ such that, when the used election method is applied to $A \setminus \{d\}$, then alternative a is still a winner.

The name for this criterion comes from the fact that — when the used election method satisfies this criterion and when alternative $a \in A$ is a winner and alternative $d(1) \in A \setminus \{a\}$ is an alternative such that, when the used election method is applied to $A \setminus \{d(1)\}$, then alternative a is still a winner — the same criterion can then be applied to $A \setminus \{d(1)\}$ to identify an alternative $d(2) \in A \setminus \{a, d(1)\}$ such that, when the used election method is applied to $A \setminus \{d(1), d(2)\}$, then alternative a is still a winner. When we continue applying this criterion, we get a linear order $d(1), \dots, d(C-1)$ of the alternatives in $A \setminus \{a\}$ such that, for every $i \in \{1, \dots, (C-1)\}$, alternative a is still a winner when the used election method is applied to $A \setminus \{d(1), \dots, d(i)\}$.

The motivation for this criterion is that an alternative $a \in A$ should be able to win only by disqualifying all the other alternatives directly or indirectly in some manner. It should not be possible that some alternatives $\emptyset \neq \{d(1), \dots, d(i)\} \subsetneq A$ disqualify each other in such a manner that the final winner comes from outside of $\{d(1), \dots, d(i)\}$. When increasing sequential independence is satisfied, then one alternative after the other is disqualified, so that the final winner $a \in A$ can come from outside of $\{d(1), \dots, d(i)\}$ only when the last remaining alternative $d(j) \in \{d(1), \dots, d(i)\}$ is disqualified by some alternatives outside of $\{d(1), \dots, d(i)\}$.

Increasing sequential independence and decreasing sequential independence (section 4.15) as criteria for single-winner election methods have been proposed by Arrow and Raynaud (1986).

Definition #1:

An election method satisfies the first version of *increasing sequential independence* if the following holds:

Suppose alternative $a \in A$ is a unique winner when this election method is applied to A . Then there must be a (not necessarily unique) alternative $d \in A \setminus \{a\}$ such that, when this election method is applied to $A \setminus \{d\}$, then alternative a is still a unique winner.

In short:

$$(4.13.1) \quad \forall a \in A: ((S = \{a\}) \Rightarrow (\exists d \in A \setminus \{a\}: S_{(A \setminus \{d\})} = \{a\})).$$

Claim #1:

The Schulze method, as defined in section 2.2, satisfies the first version of increasing sequential independence.

Proof of claim #1:

Suppose alternative $a \in A$ is a unique winner when this election method is applied to A . Then, according to (4.1.15), alternative a disqualifies every other alternative $b \in A \setminus \{a\}$. Therefore, we get

$$(4.13.2) \quad \forall b \in A \setminus \{a\}: P_D^{\text{old}}[a, b] >_D P_D^{\text{old}}[b, a].$$

Suppose $\text{pred}^{\text{old}}[a, x]$ is the predecessor of alternative $x \in A \setminus \{a\}$ in the strongest path from alternative a to alternative x , as calculated in section 2.3.1. Then a *leaf* is an alternative $y \in A \setminus \{a\}$ such that there is no alternative $x \in A \setminus \{a\}$ with $\text{pred}^{\text{old}}[a, x] = y$. As the strongest paths from alternative a to every other alternative $x \in A \setminus \{a\}$, as calculated by the Floyd-Warshall algorithm, form an arborescence, there must be at least one leaf. Alternative d is chosen arbitrarily from these leaves.

Suppose alternative d is removed. As alternative d is a leaf, alternative d is not in the strongest path from alternative a to any other alternative $b \in A \setminus \{a, d\}$. Therefore, we get

$$(4.13.3) \quad \forall b \in A \setminus \{a, d\}: P_D^{\text{new}}[a, b] \approx_D P_D^{\text{old}}[a, b].$$

On the other side, when an alternative is removed, then the strengths of the strongest paths can only decrease. Therefore, we get

$$(4.13.4) \quad \forall b \in A \setminus \{a, d\}: P_D^{\text{new}}[b, a] \lesssim_D P_D^{\text{old}}[b, a].$$

With (4.13.3), (4.13.2), and (4.13.4), we get

$$(4.13.5) \quad \forall b \in A \setminus \{a, d\}: P_D^{\text{new}}[a, b] \approx_D P_D^{\text{old}}[a, b] >_D P_D^{\text{old}}[b, a] \lesssim_D P_D^{\text{new}}[b, a]$$

so that alternative a is still a unique winner when alternative d is removed. $\square$

Definition #2:

An election method satisfies the second version of *increasing sequential independence* if the following holds:

Suppose alternative $a \in A$ is a potential winner when this election method is applied to A . Then there must be a (not necessarily unique) alternative $d \in A \setminus \{a\}$ such that, when this election method is applied to $A \setminus \{d\}$, then alternative a is still a potential winner.

In short:

$$(4.13.6) \quad \forall a \in A: ((a \in \mathcal{S}) \Rightarrow (\exists d \in A \setminus \{a\}: a \in \mathcal{S}_{(A \setminus \{d\})})).$$

Claim #2:

The Schulze method, as defined in section 2.2, satisfies the second version of increasing sequential independence.

Proof of claim #2:

Suppose alternative $a \in A$ is a potential winner when this election method is applied to A . Then, we get

$$(4.13.7) \quad \forall b \in A \setminus \{a\}: P_D^{\text{old}}[a, b] \succsim_D P_D^{\text{old}}[b, a].$$

The rest of this proof is identical to the proof of claim #1. □

4.14. k -Consistency

The Condorcet criterion says that, when some candidate $a \in A$ wins every head-to-head contest, then this candidate a should also be the overall winner (Condorcet, 1785).

However, many countries have a strong 3-party, 4-party or 5-party system where no single party can win a majority and where every party is willing to coalesce with every other party. In such a scenario, it seems to be rather uninteresting which candidate might win in a head-to-head contest. It is more interesting to ask whether there is some candidate who wins regardless of which candidates are nominated by the other parties.

So for example in the 3-party case with party α , party β , and party γ , it might be more interesting to ask whether there is a candidate from party α who wins every 3-way contest between himself and a candidate from party β and a candidate from party γ . If there is such a candidate, then this candidate should also be the overall winner.

More generally, if there is a $k \in \mathbb{N}$ with $k \geq 2$ such that there is an alternative $a \in A$ such that alternative a wins every k -way contest, then alternative a should also be the overall winner. This criterion is called *k-set-consistency* (Heitzig, 2004b) or *k-consistency* (Simmons, 2004).

k -consistency as a criterion for single-winner election methods has been proposed by Heitzig (2004b) and Simmons (2004). However, a similar idea had already been formulated by Saari (Saari, 2001, pages 154–156; Lagerspetz, 2015, page 207, footnote 20). To question the relevance of the Condorcet criterion, Saari argued that it could happen that some alternative $a \in A$ wins every 2-way contest, some other alternative $b \in A \setminus \{a\}$ wins every 3-way contest, some other alternative $c \in A \setminus \{a, b\}$ wins every 4-way contest, etc., so that, with the same justification, every alternative could claim to be the overall winner. However, the fact that the Schulze method satisfies k -consistency for every $k \in \mathbb{N}$ with $k \geq 2$ means that there are election methods where it is impossible to create examples such that there are $m, n \in \mathbb{N}$ with $2 \leq m < n \leq C$ such that some alternative $a \in A$ wins every m -way contest and some other alternative $b \in A \setminus \{a\}$ wins every n -way contest. So for these election methods, Saari’s scenario is not possible, so that his criticism of the Condorcet criterion doesn’t work.

There are five different versions for k -consistency.

The first version addresses unique winners. This version says that, when alternative $a \in A$ is a unique winner in every k -way contest, then alternative a should also be a unique winner overall. For $k = 2$, the first version of k -consistency is identical to the Condorcet criterion; equation (4.8.7)(i).

The second version addresses potential winners. This version says that, when alternative $a \in A$ is a potential winner in every k -way contest, then alternative a should also be a potential winner overall. For $k = 2$, the second version of k -consistency is identical to the desideratum that weak Condorcet winners should always be potential winners; equation (4.12.1.6).

The third version addresses the set of potential winners. This version says that, when in every k -way contest (that contains at least one alternative of the set $\emptyset \neq B \subsetneq A$) the winner comes from the set B , then the winner must also come from the set B when the method is applied to A . For $k = 2$, the third version of k -consistency is identical to the Smith criterion; equation (4.8.5).

The fourth version says that, when alternative $a \in A$ is not a unique winner in any k -way contest, then alternative a should also be not a unique winner overall. For $k = 2$, the fourth version of k -consistency is identical to the desideratum that a weak Condorcet loser should not be a unique winner; equation (4.12.2.13).

The fifth version says that, when alternative $a \in A$ is not a potential winner in any k -way contest, then alternative a should also be not a potential winner overall. For $k = 2$, the fifth version of k -consistency is identical to the Condorcet loser criterion; equation (4.8.9)(i).

4.14.1. Formulation #1

Definition:

Suppose $k \in \mathbb{N}$ with $k \geq 2$. An election method satisfies the first version of k -consistency if the following holds:

Suppose C with $C > k$ is the number of alternatives in A . Suppose alternative $a \in A$ is a unique winner whenever this election method is applied to some subset $\tilde{A} \subset A$ with $\|\tilde{A}\| = k$ and $a \in \tilde{A}$. Then alternative a is also a unique winner when this election method is applied to A .

In short:

$$(4.14.1.1) \quad \forall a \in A: ((\forall \tilde{A} \subset A \text{ with } \|\tilde{A}\| = k \\ \text{and } a \in \tilde{A}: S|_{\tilde{A}} = \{a\}) \Rightarrow (S = \{a\})).$$

Claim:

If $>_D$ satisfies (2.1.5), then the Schulze method, as defined in section 2.2, satisfies the first version of k -consistency for every $k \in \mathbb{N}$ with $k \geq 2$.

Proof (overview):

We will show how, when alternative $a \in A$ is not a unique winner (when this election method is applied to A), we can create, for every $k \in \mathbb{N}$ with $2 \leq k < C$, a subset $\tilde{A} \subset A$ with $\|\tilde{A}\| = k$ and $a \in \tilde{A}$ such that, when the Schulze method is applied to $\tilde{A}$, alternative a is not a unique winner.

Proof (details):

Suppose alternative $a \in A$ is not a unique winner when the Schulze method is applied to A . Then, with (4.1.15), we get that there must be an alternative $b \in A \setminus \{a\}$ with

$$(4.14.1.2) \quad P_D[b, a] \approx_D P_D[a, b].$$

We set

$$(4.14.1.3) \quad (z_1, z_2) := P_D[b, a]$$

to stress that this value is constant for the rest of this proof.

Suppose $c(1), \dots, c(n)$ is the shortest path (in terms of its number of links) from alternative $b \equiv c(1)$ to alternative $a \equiv c(n)$ of strength (z_1, z_2) . Then we get

$$(4.14.1.4) \quad \forall i = 1, \dots, (n-1): (N[c(i), c(i+1)], N[c(i+1), c(i)]) \approx_D (z_1, z_2).$$

Especially, we get

$$(4.14.1.5) \quad (N[c(n-1), c(n)], N[c(n), c(n-1)]) \approx_D (z_1, z_2).$$

Furthermore, we get

$$(4.14.1.6) \quad \forall i, j \in \{1, \dots, n\} \text{ with } j - i \geq 2: (N[c(i), c(j)], N[c(j), c(i)]) <_D (z_1, z_2).$$

Otherwise, if there was a link $c(i), c(j)$ with $(N[c(i), c(j)], N[c(j), c(i)]) \approx_D (z_1, z_2)$ and $j - i \geq 2$, then we could find a shorter path of strength (z_1, z_2) by omitting the alternatives $c(i+1), \dots, c(j-1)$. This would be a contradiction to the presumption that $c(1), \dots, c(n)$ is the shortest path of strength (z_1, z_2) .

With (2.1.5), we get that every path that contains no defeat is always stronger than every path that contains a defeat.

It is easy to prove that the path $c(1), \dots, c(n)$ contains no defeat. Therefore, we get

$$(4.14.1.7) \quad \forall i = 1, \dots, (n-1): N[c(i), c(i+1)] \geq N[c(i+1), c(i)].$$

Proof for (4.14.1.7):

To prove that the path $c(1), \dots, c(n)$ contains no defeat, we presume that (2.1.5) and (4.14.1.2) are satisfied and that the path $c(1), \dots, c(n)$ contains a defeat and then we will show that this leads to a contradiction.

To get to a contradiction, it is sufficient to consider the link ab .

Case #A: If the link ab is a victory (i.e. $N[a, b] > N[b, a]$), then this link is already a path from alternative a to alternative b that contains no defeat. Therefore, with (2.1.5) and the fact that the path $c(1), \dots, c(n)$ contains a defeat, we get $P_D[a, b] \approx_D (N[a, b], N[b, a]) >_D P_D[b, a]$. But this is a contradiction to (4.14.1.2).

Case #B: If the link ab is a defeat (i.e. $N[a, b] < N[b, a]$) or a tie (i.e. $N[a, b] = N[b, a]$), then the link ba is a path from alternative b to alternative a that contains no defeat. But then, according to (2.1.5), the link ba is stronger than the path $c(1), \dots, c(n)$ that contains a defeat. But this is a contradiction to the presumption that the path $c(1), \dots, c(n)$ is a strongest path from alternative b to alternative a .

With (4.14.1.7), we get

$$(4.14.1.8) \quad N[c(n-1), c(n)] \geq N[c(n), c(n-1)].$$

With (2.1.5) and (4.14.1.8), we get

$$(4.14.1.9) \quad (N[c(n-1), c(n)], N[c(n), c(n-1)]) \approx_D (N[c(n), c(n-1)], N[c(n-1), c(n)]).$$

With the above considerations, we can now show how the subset $\tilde{A} \subset A$ can be chosen.

Case #1: $k = 2$.

The first version of 2-consistency is identical to the Condorcet criterion, as formulated in (4.8.7)(i). However, it has already been proven in section 4.8 that, when $\succ_D$ satisfies (2.1.5), then the Schulze method satisfies (4.8.7)(i).

Case #2: $3 \leq k < n$.

Here, we choose $\tilde{A} := \{c(1), \dots, c(k-2), c(n-1), c(n)\}$.

When the Schulze method is applied to $\tilde{A}$, then there is a path from $c(n-1)$ to $a \equiv c(n)$ of at least $(N[c(n-1), c(n)], N[c(n), c(n-1)]) \approx_D (z_1, z_2)$ because, according to (4.14.1.5), already the link $c(n-1), c(n)$ is a path from $c(n-1)$ to $c(n)$ of this strength.

On the other side, there cannot be a path in $\tilde{A}$ from $a \equiv c(n)$ to $c(n-1)$ of more than $(N[c(n-1), c(n)], N[c(n), c(n-1)])$ because, according to (4.14.1.6), every link from $c(1), \dots, c(k-2)$ to $c(n-1)$ is weaker than (z_1, z_2) and, according to (4.14.1.9), the link $c(n), c(n-1)$ is not stronger than $(N[c(n-1), c(n)], N[c(n), c(n-1)])$.

Therefore, alternative $a \equiv c(n)$ cannot disqualify alternative $c(n-1)$. So either alternative $c(n-1)$ is also a potential winner or, according to (4.1.14), alternative $c(n-1)$ must be disqualified by some other potential winner. In both cases, alternative $a \equiv c(n)$ is not a unique winner.

Case #3: $k \geq n$.

Here, $\tilde{A}$ consists of the alternatives $c(1), \dots, c(n)$ and $k-n$ additional alternatives from A .

As $\{c(1), \dots, c(n)\} \subseteq \tilde{A}$, there is a path in $\tilde{A}$ from alternative $b \equiv c(1)$ to alternative $a \equiv c(n)$ of strength (z_1, z_2) . On the other side, we get, with (4.14.1.2), that there cannot be a path in $\tilde{A}$ from alternative $a \equiv c(n)$ to alternative $b \equiv c(1)$ of more than (z_1, z_2) because, when alternatives are removed from A , then the strength of the strongest path from alternative $a \equiv c(n)$ to alternative $b \equiv c(1)$ can only decrease.

Therefore, alternative $a \equiv c(n)$ cannot disqualify alternative $b \equiv c(1)$ in $\tilde{A}$. So either alternative $b \equiv c(1)$ is also a potential winner or, according to (4.1.14), alternative $b \equiv c(1)$ must be disqualified by some other potential winner. In both cases, alternative $a \equiv c(n)$ is not a unique winner. $\square$

4.14.2. Formulation #2

Definition:

Suppose $k \in \mathbb{N}$ with $k \geq 2$. An election method satisfies the second version of k -consistency if the following holds:

Suppose C with $C > k$ is the number of alternatives in A . Suppose alternative $a \in A$ is a potential winner whenever this election method is applied to some subset $\tilde{A} \subset A$ with $\|\tilde{A}\| = k$ and $a \in \tilde{A}$. Then alternative a is also a potential winner when this election method is applied to A .

In short:

$$(4.14.2.1) \quad \forall a \in A: ((\forall \tilde{A} \subset A \text{ with } \|\tilde{A}\| = k \text{ and } a \in \tilde{A}: a \in \mathcal{S}_{\tilde{A}}) \Rightarrow (a \in \mathcal{S})).$$

Claim:

If $>_D$ satisfies (2.1.4) and (2.1.5), then the Schulze method, as defined in section 2.2, satisfies the second version of k -consistency for every $k \in \mathbb{N}$ with $k \geq 2$.

Proof (overview):

We will show how, when alternative $a \in A$ is not a potential winner (when this election method is applied to A), we can create, for every $k \in \mathbb{N}$ with $2 \leq k < C$, a subset $\tilde{A} \subset A$ with $\|\tilde{A}\| = k$ and $a \in \tilde{A}$ such that, when the Schulze method is applied to $\tilde{A}$, alternative a is not a potential winner.

Proof (details):

Suppose alternative $a \in A$ is not a potential winner when the Schulze method is applied to A . Then, with (2.2.2), we get that there must be an alternative $b \in A \setminus \{a\}$ with

$$(4.14.2.2) \quad P_D[b, a] >_D P_D[a, b].$$

We set

$$(4.14.2.3) \quad (z_1, z_2) := P_D[b, a]$$

to stress that this value is constant for the rest of this proof.

Suppose $c(1), \dots, c(n)$ is the shortest path (in terms of its number of links) from alternative $b \equiv c(1)$ to alternative $a \equiv c(n)$ of strength (z_1, z_2) . Then we get

$$(4.14.2.4) \quad \forall i = 1, \dots, (n-1): (N[c(i), c(i+1)], N[c(i+1), c(i)]) \approx_D (z_1, z_2).$$

Especially, we get

$$(4.14.2.5) \quad (N[c(n-1), c(n)], N[c(n), c(n-1)]) \approx_D (z_1, z_2).$$

Furthermore, we get

$$(4.14.2.6) \quad \forall i, j \in \{1, \dots, n\} \text{ with } j - i \geq 2: (N[c(i), c(j)], N[c(j), c(i)]) <_D (z_1, z_2).$$

Otherwise, if there was a link $c(i), c(j)$ with $(N[c(i), c(j)], N[c(j), c(i)]) \approx_D (z_1, z_2)$ and $j - i \geq 2$, then we could find a shorter path of strength (z_1, z_2) by omitting the alternatives $c(i+1), \dots, c(j-1)$. This would be a contradiction to the presumption that $c(1), \dots, c(n)$ is the shortest path of strength (z_1, z_2) .

With (2.1.4) and (2.1.5), we get that every path that contains no defeat or tie is always stronger than every path that contains a defeat or tie.

It is easy to prove that the path $c(1), \dots, c(n)$ contains no defeat or tie. Therefore, we get

$$(4.14.2.7) \quad \forall i = 1, \dots, (n-1): N[c(i), c(i+1)] > N[c(i+1), c(i)].$$

Proof for (4.14.2.7):

To prove that the path $c(1), \dots, c(n)$ contains no defeat or tie, we presume that (2.1.4), (2.1.5), and (4.14.2.2) are satisfied and that the path $c(1), \dots, c(n)$ contains a defeat or tie and then we will show that this leads to a contradiction.

(2.1.4) says that all ties have equivalent strengths. (2.1.5) says that every victory is stronger than every tie and that every tie is stronger than every defeat. So when the path $c(1), \dots, c(n)$ contains a defeat or tie then, without loss of generality, we can set

$$(4.14.2.8) \quad P_D[b, a] \approx_D (1, 1).$$

To get to a contradiction, it is sufficient to consider the link ab .

Case #A: If the link ab is a victory (i.e. $N[a, b] > N[b, a]$) or a tie (i.e. $N[a, b] = N[b, a]$), then this link is already a path from alternative a to alternative b that contains no defeat. Therefore, with (2.1.4), (2.1.5), and (4.14.2.8), we get $P_D[a, b] \approx_D (N[a, b], N[b, a]) \approx_D (1, 1) \approx_D P_D[b, a]$. But this is a contradiction to (4.14.2.2).

Case #B: If the link ab is a defeat (i.e. $N[a, b] < N[b, a]$), then the link ba is a path from alternative b to alternative a that contains no defeat or tie. But then, according to (2.1.5), the link ba is stronger than the path $c(1), \dots, c(n)$ that contains a defeat or tie. But this is a contradiction to the presumption that the path $c(1), \dots, c(n)$ is a strongest path from alternative b to alternative a .

With (4.14.2.7), we get

$$(4.14.2.9) \quad N[c(n-1), c(n)] > N[c(n), c(n-1)].$$

With (2.1.5) and (4.14.2.9), we get

$$(4.14.2.10) \quad (N[c(n-1),c(n)],N[c(n),c(n-1)]) \\ \succ_D (N[c(n),c(n-1)],N[c(n-1),c(n)]).$$

With the above considerations, we can now show how the subset $\tilde{A} \subset A$ can be chosen.

Case #1: $k = 2$.

The second version of 2-consistency says that a weak Condorcet winner should always be a potential winner, as formulated in (4.12.1.6). However, it has already been proven in section 4.12.1 that, when $\succ_D$ satisfies (2.1.4) and (2.1.5), then the Schulze method satisfies (4.12.1.6).

Case #2: $3 \leq k < n$.

Here, we choose $\tilde{A} := \{c(1), \dots, c(k-2), c(n-1), c(n)\}$.

When the Schulze method is applied to $\tilde{A}$, then there is a path from $c(n-1)$ to $a \equiv c(n)$ of at least $(N[c(n-1),c(n)],N[c(n),c(n-1)]) \succ_D (z_1, z_2)$ because, according to (4.14.2.5), already the link $c(n-1), c(n)$ is a path from $c(n-1)$ to $c(n)$ of this strength.

On the other side, there cannot be a path in $\tilde{A}$ from $a \equiv c(n)$ to $c(n-1)$ of at least $(N[c(n-1),c(n)],N[c(n),c(n-1)])$ because, according to (4.14.2.6), every link from $c(1), \dots, c(k-2)$ to $c(n-1)$ is weaker than (z_1, z_2) and, according to (4.14.2.10), the link $c(n), c(n-1)$ is weaker than $(N[c(n-1),c(n)],N[c(n),c(n-1)])$.

Therefore, alternative $c(n-1)$ disqualifies alternative $a \equiv c(n)$, so that alternative $a \equiv c(n)$ is not a potential winner.

Case #3: $k \geq n$.

Here, $\tilde{A}$ consists of the alternatives $c(1), \dots, c(n)$ and $k-n$ additional alternatives from A .

As $\{c(1), \dots, c(n)\} \subseteq \tilde{A}$, there is a path in $\tilde{A}$ from alternative $b \equiv c(1)$ to alternative $a \equiv c(n)$ of strength (z_1, z_2) . On the other side, we get, with (4.14.2.2), that there cannot be a path in $\tilde{A}$ from alternative $a \equiv c(n)$ to alternative $b \equiv c(1)$ of at least (z_1, z_2) because, when alternatives are removed from A , then the strength of the strongest path from alternative $a \equiv c(n)$ to alternative $b \equiv c(1)$ can only decrease.

Therefore, alternative $b \equiv c(1)$ disqualifies alternative $a \equiv c(n)$ in $\tilde{A}$, so that alternative $a \equiv c(n)$ is not a potential winner. $\square$

4.14.3. Formulation #3

Definition:

Suppose $k \in \mathbb{N}$ with $k \geq 2$. An election method satisfies the third version of k -consistency if the following holds:

Suppose C with $C > k$ is the number of alternatives in A . Suppose $S|_{\tilde{A}}$ is the set of potential winners when this election method is applied to $\emptyset \neq \tilde{A} \subseteq A$. Suppose $\emptyset \neq B \subsetneq A$. Suppose $S|_{\tilde{A}} \subseteq B$ whenever this election method is applied to some subset $\tilde{A} \subset A$ with $\|\tilde{A}\| = k$ and $(B \cap \tilde{A}) \neq \emptyset$. Then we must also get $S \subseteq B$.

In short:

$$(4.14.3.1) \quad \forall \emptyset \neq B \subsetneq A: ((\forall \tilde{A} \subset A \text{ with } \|\tilde{A}\| = k \text{ and } (B \cap \tilde{A}) \neq \emptyset: S|_{\tilde{A}} \subseteq B) \Rightarrow (S \subseteq B)).$$

Claim:

If $>_D$ satisfies (2.1.5), then the Schulze method, as defined in section 2.2, satisfies the third version of k -consistency for every $k \in \mathbb{N}$ with $k \geq 2$.

Proof (overview):

We will show how, when $S \not\subseteq B$, we can create, for every $k \in \mathbb{N}$ with $2 \leq k < C$, a subset $\tilde{A} \subset A$ with $\|\tilde{A}\| = k$ and $(B \cap \tilde{A}) \neq \emptyset$ such that, when the Schulze method is applied to $\tilde{A}$, we get $S|_{\tilde{A}} \not\subseteq B$.

Proof (details):

Suppose $r := \|B\|$ is the number of alternatives in B . With $\emptyset \neq B \subsetneq A$, we get: $0 < r < C$.

Case #1: $k = 2$.

The third version of 2-consistency is identical to the Smith criterion, as formulated in (4.8.5). However, it has already been proven in section 4.8 that, when $>_D$ satisfies (2.1.5), then the Schulze method satisfies the Smith criterion.

Case #2: $k > C - r$.

As $k > C - r$, every set $\tilde{A} \subset A$ with $\|\tilde{A}\| = k$ contains at least $k + r - C \geq 1$ alternatives of B . Therefore, we get $(B \cap \tilde{A}) \neq \emptyset$ for every set $\tilde{A} \subset A$ with $\|\tilde{A}\| = k$.

Suppose $S \not\subseteq B$. Then there is an alternative $a \in A$ with $a \in S$ and $a \notin B$. In section 4.13, we have proven that, when alternative $a \in A$ is a potential winner, then there is a linear order $d(1), \dots, d(C-1)$ of the alternatives in $A \setminus \{a\}$ such that, when the Schulze method is applied to $A \setminus \{d(1), \dots, d(C-k)\}$, then alternative a is still a potential winner. Therefore, when we choose $\tilde{A} := A \setminus \{d(1), \dots, d(C-k)\}$, we get $a \in S|_{\tilde{A}}$. With $a \notin B$, we get $S|_{\tilde{A}} \not\subseteq B$.

Case #3: $3 \leq k \leq C - r$.

Suppose $S \not\subseteq B$. Then there must be an alternative $b \in A$ with $b \in S$ and $b \notin B$. With $b \in S$ we get

$$(4.14.3.2) \quad \forall a \in A \setminus \{b\}: P_D[b, a] \approx_D P_D[a, b].$$

Without loss of generality, we can assume that the Floyd-Warshall algorithm is used to calculate the strongest paths (as defined in section 2.3.1). We then sort the alternatives $\{a(1), \dots, a(C-1)\}$ in $A \setminus \{b\}$ such that

$$(4.14.3.3) \quad \text{pred}[b, a(j)] = a(i) \Rightarrow i < j.$$

Suppose $y \in \mathbb{N}$ with $1 \leq y < C$ is the smallest number with $a(y) \in B$. Then we get $a(x) \notin B$ for all $x \in \mathbb{N}$ with $1 \leq x < y$. Furthermore, when $g(1), \dots, g(m)$ is the strongest path from alternative $b \equiv g(1)$ to alternative $a(y) \equiv g(m)$ then, with the definition for $\text{pred}[i, j]$ and with the definition for the order of $\{a(1), \dots, a(C-1)\}$, we get $\{g(1), \dots, g(m-1)\} \subseteq \{b, a(1), \dots, a(y-1)\} \subseteq A \setminus B$.

We set

$$(4.14.3.4) \quad (z_1, z_2) := P_D[b, a(y)]$$

to stress that this value is constant for the rest of this proof.

We now shorten the path $g(1), \dots, g(m)$ by removing possible short cuts. So when there is a link $g(i), g(j)$ with $(N[g(i), g(j)], N[g(j), g(i)]) \approx_D (z_1, z_2)$ and $j - i \geq 2$, we remove the alternatives $g(i+1), \dots, g(j-1)$ from this path. We continue removing possible short cuts, until the resulting path contains no short cuts anymore. The resulting path will be called $c(1), \dots, c(n)$.

We get

$$(4.14.3.5) \quad c(i) \notin B \text{ for all } i \in \mathbb{N} \text{ with } 1 \leq i < n,$$

because we have already established $g(i) \notin B$ for all $i \in \mathbb{N}$ with $1 \leq i < m$ and because, when we shortened the path $g(1), \dots, g(m)$, we only removed and didn't add alternatives.

With the same arguments as for (4.14.1.4) – (4.14.1.9), we get (4.14.3.6) – (4.14.3.11):

$$(4.14.3.6) \quad \forall i = 1, \dots, (n-1): (N[c(i), c(i+1)], N[c(i+1), c(i)]) \approx_D (z_1, z_2).$$

$$(4.14.3.7) \quad (N[c(n-1), c(n)], N[c(n), c(n-1)]) \approx_D (z_1, z_2).$$

$$(4.14.3.8) \quad \forall i, j \in \{1, \dots, n\} \text{ with } j - i \geq 2: (N[c(i), c(j)], N[c(j), c(i)]) <_D (z_1, z_2).$$

$$(4.14.3.9) \quad \forall i = 1, \dots, (n-1): N[c(i), c(i+1)] \geq N[c(i+1), c(i)].$$

$$(4.14.3.10) \quad N[c(n-1), c(n)] \geq N[c(n), c(n-1)].$$

$$(4.14.3.11) \quad (N[c(n-1), c(n)], N[c(n), c(n-1)]) \approx_D (N[c(n), c(n-1)], N[c(n-1), c(n)]).$$

With the above considerations, we can now show how the subset $\tilde{A} \subset A$ can be chosen.

Case #3a: $3 \leq k \leq C - r$ with $k < n$.

Here, we choose $\tilde{A} := \{c(1), \dots, c(k-2), c(n-1), c(n)\}$.

With $c(n) \equiv a(y) \in B$, we get $(B \cap \tilde{A}) \neq \emptyset$.

When the Schulze method is applied to $\tilde{A}$, then there is a path from $c(n-1)$ to $c(n)$ of at least $(N[c(n-1), c(n)], N[c(n), c(n-1)]) \succeq_D (z_1, z_2)$ because, according to (4.14.3.7), already the link $c(n-1), c(n)$ is a path from $c(n-1)$ to $c(n)$ of this strength.

On the other side, there cannot be a path in $\tilde{A}$ from $c(n)$ to $c(n-1)$ of more than $(N[c(n-1), c(n)], N[c(n), c(n-1)])$ because, according to (4.14.3.8), every link from $c(1), \dots, c(k-2)$ to $c(n-1)$ is weaker than (z_1, z_2) and, according to (4.14.3.11), the link $c(n), c(n-1)$ is not stronger than $(N[c(n-1), c(n)], N[c(n), c(n-1)])$.

Therefore, alternative $c(n)$ cannot disqualify alternative $c(n-1)$. So either alternative $c(n-1)$ is also a potential winner or, according to (4.1.14), alternative $c(n-1)$ must be disqualified by some other potential winner in $\tilde{A}$. With (4.14.3.5) we get that this potential winner comes from outside B . So we get $\mathcal{S}_{|\tilde{A}} \not\subseteq B$.

Case #3b: $3 \leq k \leq C - r$ with $n \leq k$.

Here, $\tilde{A}$ consists of the alternatives $c(1), \dots, c(n)$ and $k-n$ additional alternatives from $A \setminus B$.

With $c(n) \equiv a(y) \in B$, we get $(B \cap \tilde{A}) \neq \emptyset$.

As $\{c(1), \dots, c(n)\} \subseteq \tilde{A}$, there is a path in $\tilde{A}$ from alternative $b \equiv c(1)$ to alternative $a(y) \equiv c(n)$ of strength (z_1, z_2) . On the other side, we get, with (4.14.3.2), that there cannot be a path in $\tilde{A}$ from alternative $a(y) \equiv c(n)$ to alternative $b \equiv c(1)$ of more than (z_1, z_2) because, when alternatives are removed from A , then the strength of the strongest path from alternative $a(y) \equiv c(n)$ to alternative $b \equiv c(1)$ can only decrease.

Therefore, alternative $a(y) \equiv c(n)$ cannot disqualify alternative $b \equiv c(1)$. So either alternative $b \equiv c(1)$ is also a potential winner or, according to (4.1.14), alternative $b \equiv c(1)$ must be disqualified by some other potential winner in $\tilde{A}$. With (4.14.3.5) we get that this potential winner comes from outside B . So we get $\mathcal{S}_{|\tilde{A}} \not\subseteq B$. $\square$

4.14.4. Formulation #4

Definition:

Suppose $k \in \mathbb{N}$ with $k \geq 2$. An election method satisfies the fourth version of k -consistency if the following holds:

Suppose C with $C > k$ is the number of alternatives in A . Suppose alternative $a \in A$ is not a unique winner whenever this election method is applied to some subset $\tilde{A} \subset A$ with $\|\tilde{A}\| = k$ and $a \in \tilde{A}$. Then alternative a is also not a unique winner when this election method is applied to A .

In short:

$$(4.14.4.1) \quad \forall a \in A: ((\forall \tilde{A} \subset A \text{ with } \|\tilde{A}\| = k \\ \text{and } a \in \tilde{A}: S_{|\tilde{A}} \neq \{a\}) \Rightarrow (S \neq \{a\})).$$

Claim:

The Schulze method, as defined in section 2.2, satisfies the fourth version of k -consistency for every $k \in \mathbb{N}$ with $k \geq 2$.

Remark:

Presumptions (2.1.4) and (2.1.5) are not needed in the following proof. However, only when $>_D$ satisfies (2.1.4) and (2.1.5), the fourth version of k -consistency with $k = 2$ is identical to the desideratum that a weak Condorcet loser should not be a unique winner; equation (4.12.2.13).

Proof (overview):

We will show how, when alternative $a \in A$ is a unique winner (when this election method is applied to A), we can create, for every $k \in \mathbb{N}$ with $2 \leq k < C$, a subset $\tilde{A} \subset A$ with $\|\tilde{A}\| = k$ and $a \in \tilde{A}$ such that, when the Schulze method is applied to $\tilde{A}$, alternative a is a unique winner.

Proof (details):

In section 4.13 (definition #1), we have proven that, when alternative $a \in A$ is a unique winner, then there is a linear order $d(1), \dots, d(C-1)$ of the alternatives in $A \setminus \{a\}$ such that, for every $i \in \{1, \dots, (C-1)\}$, alternative a is still a unique winner when the Schulze method is applied to $A \setminus \{d(1), \dots, d(i)\}$.

Therefore, for $k \in \mathbb{N}$ with $2 \leq k < C$, we can simply choose $\tilde{A} := A \setminus \{d(1), \dots, d(C-k)\}$. $\square$

4.14.5. Formulation #5

Definition:

Suppose $k \in \mathbb{N}$ with $k \geq 2$. An election method satisfies the fifth version of k -consistency if the following holds:

Suppose C with $C > k$ is the number of alternatives in A . Suppose alternative $a \in A$ is not a potential winner whenever this election method is applied to some subset $\tilde{A} \subset A$ with $\|\tilde{A}\| = k$ and $a \in \tilde{A}$. Then alternative a is also not a potential winner when this election method is applied to A .

In short:

$$(4.14.5.1) \quad \forall a \in A: ((\forall \tilde{A} \subset A \text{ with } \|\tilde{A}\| = k \text{ and } a \in \tilde{A}: a \notin S_{|\tilde{A}}) \Rightarrow (a \notin S)).$$

Claim:

The Schulze method, as defined in section 2.2, satisfies the fifth version of k -consistency for every $k \in \mathbb{N}$ with $k \geq 2$.

Remark:

Presumption (2.1.5) is not needed in the following proof. However, only when $>_D$ satisfies (2.1.5), the fifth version of k -consistency with $k = 2$ is identical to the Condorcet loser criterion; equation (4.8.9)(i).

Proof (overview):

We will show how, when alternative $a \in A$ is a potential winner (when this election method is applied to A), we can create, for every $k \in \mathbb{N}$ with $2 \leq k < C$, a subset $\tilde{A} \subset A$ with $\|\tilde{A}\| = k$ and $a \in \tilde{A}$ such that, when the Schulze method is applied to $\tilde{A}$, alternative a is a potential winner.

Proof (details):

In section 4.13 (definition #2), we have proven that, when alternative $a \in A$ is a potential winner, then there is a linear order $d(1), \dots, d(C-1)$ of the alternatives in $A \setminus \{a\}$ such that, for every $i \in \{1, \dots, (C-1)\}$, alternative a is still a potential winner when the Schulze method is applied to $A \setminus \{d(1), \dots, d(i)\}$.

Therefore, for $k \in \mathbb{N}$ with $2 \leq k < C$, we can simply choose $\tilde{A} := A \setminus \{d(1), \dots, d(C-k)\}$. $\square$

4.15. Decreasing Sequential Independence

Decreasing sequential independence says that, when alternative $a \in A$ is not a winner, then there must be an alternative $e \in A \setminus \{a\}$ such that, when the used election method is applied to $A \setminus \{e\}$, then alternative a is still not a winner.

The name for this criterion comes from the fact that — when the used election method satisfies this criterion and when alternative $a \in A$ is not a winner and alternative $e(1) \in A \setminus \{a\}$ is an alternative such that, when the used election method is applied to $A \setminus \{e(1)\}$, then alternative a is still not a winner — the same criterion can then be applied to $A \setminus \{e(1)\}$ to identify an alternative $e(2) \in A \setminus \{a, e(1)\}$ such that, when the used election method is applied to $A \setminus \{e(1), e(2)\}$, then alternative a is still not a winner. When we continue applying this criterion, we get a linear order $e(1), \dots, e(C-2)$ of the alternatives in $A \setminus \{a, e(C-1)\}$ (where $e(C-1) \in A \setminus \{a, e(1), \dots, e(C-2)\}$ is the last remaining alternative to disqualify alternative a) such that, for every $i \in \{1, \dots, (C-2)\}$, alternative a is still not a winner when the used election method is applied to $A \setminus \{e(1), \dots, e(i)\}$.

Increasing sequential independence (section 4.13) and decreasing sequential independence address opposite problems. On the one side, *increasing sequential independence* says that it should not be possible that alternatives $\emptyset \neq \{d(1), \dots, d(i)\} \subsetneq A$ harm each other in such a manner that the final winner comes from outside of $\{d(1), \dots, d(i)\}$. On the other side, *decreasing sequential independence* says that, when no proper subset of $\{e(1), \dots, e(i)\}$ can disqualify alternative $a \in A \setminus \{e(1), \dots, e(i)\}$, then the alternatives $\{e(1), \dots, e(i)\}$ should not *help* each other in such a manner that $\{e(1), \dots, e(i)\}$ together disqualify this alternative.

The fact that the Schulze method satisfies decreasing sequential independence follows directly from the fact that the Schulze method satisfies the first and the second version of k -consistency for every $k \in \mathbb{N}$ with $2 \leq k < C$ (sections 4.14.1 and 4.14.2).

Definition #1:

An election method satisfies the first version of *decreasing sequential independence* if the following holds:

Suppose there are at least $C \geq 3$ alternatives. Suppose alternative $a \in A$ is not a unique winner when this election method is applied to A . Then there must be a (not necessarily unique) alternative $e \in A \setminus \{a\}$ such that, when this election method is applied to $A \setminus \{e\}$, then alternative a is still not a unique winner.

In short:

$$(4.15.1) \quad \forall C \geq 3 \forall a \in A: \\ ((S \neq \{a\}) \Rightarrow (\exists e \in A \setminus \{a\}: S|_{(A \setminus \{e\})} \neq \{a\})).$$

Claim #1:

If $>_D$ satisfies (2.1.5), then the Schulze method, as defined in section 2.2, satisfies the first version of decreasing sequential independence.

Proof of claim #1:

Suppose that the Schulze method violates (4.15.1). Then there must be a $C \geq 3$ such that there is an $a \in A$ with $\mathcal{S} \neq \{a\}$ and

$$(4.15.2) \quad \forall e \in A \setminus \{a\}: \mathcal{S}|_{(A \setminus \{e\})} = \{a\}.$$

With (4.14.1.1), (4.15.2) and $k := C - 1 \geq 2$, we get: $\mathcal{S} = \{a\}$. But this is a contradiction to the presumption $\mathcal{S} \neq \{a\}$. $\square$

Definition #2:

An election method satisfies the second version of *decreasing sequential independence* if the following holds:

Suppose there are at least $C \geq 3$ alternatives. Suppose alternative $a \in A$ is not a potential winner when this election method is applied to A . Then there must be a (not necessarily unique) alternative $e \in A \setminus \{a\}$ such that, when this election method is applied to $A \setminus \{e\}$, then alternative a is still not a potential winner.

In short:

$$(4.15.3) \quad \forall C \geq 3 \forall a \in A: \\ ((a \notin \mathcal{S}) \Rightarrow (\exists e \in A \setminus \{a\}: a \notin \mathcal{S}|_{(A \setminus \{e\})})).$$

Claim #2:

If $>_D$ satisfies (2.1.4) and (2.1.5), then the Schulze method, as defined in section 2.2, satisfies the second version of decreasing sequential independence.

Proof of claim #2:

Suppose that the Schulze method violates (4.15.3). Then there must be a $C \geq 3$ such that there is an $a \in A$ with $a \notin \mathcal{S}$ and

$$(4.15.4) \quad \forall e \in A \setminus \{a\}: a \in \mathcal{S}|_{(A \setminus \{e\})}.$$

With (4.14.2.1), (4.15.4) and $k := C - 1 \geq 2$, we get: $a \in \mathcal{S}$. But this is a contradiction to the presumption $a \notin \mathcal{S}$. $\square$

4.16. Weak Independence from Pareto-Dominated Alternatives

Suppose an alternative j is added such that:

$$(3.8.1) \quad \exists i \in A^{\text{old}} \forall v \in V: i \succ_v^{\text{new}} j.$$

$$(3.8.2) \quad \forall g, h \in A^{\text{old}} \forall v \in V: g \succ_v^{\text{old}} h \Leftrightarrow g \succ_v^{\text{new}} h.$$

Then *independence from Pareto-dominated alternatives* (IPDA) says that we must get:

$$(3.8.3) \quad \forall g, h \in A^{\text{old}}: gh \in O^{\text{old}} \Leftrightarrow gh \in O^{\text{new}}.$$

$$(3.8.4) \quad \forall g \in A^{\text{old}}: g \in S^{\text{old}} \Leftrightarrow g \in S^{\text{new}}.$$

In example 8 (section 3.8) and example 9 (section 3.9), we have seen that the Schulze method violates IPDA. In example 8, the winner is changed from alternative $a \in A^{\text{old}}$ to alternative $b \in A^{\text{old}} \setminus \{a\}$ by adding an alternative e with

$$(4.16.1) \quad \exists d \in A^{\text{old}} \setminus \{a, b\} \forall v \in V: d \succ_v^{\text{new}} e.$$

In example 9, the winner is changed from alternative $a \in A^{\text{old}}$ to alternative $b \in A^{\text{old}} \setminus \{a\}$ by adding an alternative e with

$$(4.16.2) \quad \forall v \in V: a \succ_v^{\text{new}} e.$$

It has already been mentioned in section 4.9 that IPDA and (4.9.5) are incompatible. In example 8(old), we have $\mathfrak{B}_D^{\text{old}} = \{a, c, d\}$. In example 8(new), we have $\mathfrak{B}_D^{\text{new}} = \{b\}$. Therefore, $(\mathfrak{B}_D^{\text{old}} \cap \mathfrak{B}_D^{\text{new}}) = \emptyset$. So (4.9.5) says that the winner must change. In example 9(old), we have $\mathfrak{B}_D^{\text{old}} = \{a, c, d\}$. In example 9(new), we have $\mathfrak{B}_D^{\text{new}} = \{b\}$ so that, again, (4.9.5) says that the winner must change.

So we cannot exclude that the winner is changed from alternative $a \in A^{\text{old}}$ to alternative $b \in A^{\text{old}} \setminus \{a\}$ by adding an alternative e with (4.16.1) or (4.16.2). But we will prove that the winner cannot be changed from alternative $a \in A^{\text{old}}$ to alternative $b \in A^{\text{old}} \setminus \{a\}$ by adding an alternative e with

$$(4.16.3) \quad \forall v \in V: b \succ_v^{\text{new}} e.$$

Definition:

An election method satisfies *weak independence from Pareto-dominated alternatives* (wIPDA) if the following holds:

Suppose $b \notin S^{\text{old}}$.

Suppose an alternative e is added with (3.8.2) and

$$(4.16.4) \quad \forall v \in V: b \succ_v^{\text{new}} e.$$

Then we get: $b \notin S^{\text{new}}$.

Claim:

If $\succ_D$ satisfies (2.1.1), then the Schulze method, as defined in section 2.2, satisfies *weak independence from Pareto-dominated alternatives*.

Proof:

Suppose $b \notin S^{\text{old}}$. Then, there was an alternative $a \in A^{\text{old}} \setminus \{b\}$ with $ab \in O^{\text{old}}$. With $ab \in O^{\text{old}}$, we get

$$(4.16.5) \quad P_D^{\text{old}}[a,b] \succ_D P_D^{\text{old}}[b,a].$$

Suppose an alternative e is added with (3.8.2) and (4.16.4).

Suppose $c(1), \dots, c(n)$ was the strongest path from alternative a to alternative b in A^{old} . Then $c(1), \dots, c(n)$ is still a path from alternative a to alternative b in A^{new} of the same strength. Therefore, we get

$$(4.16.6) \quad P_D^{\text{new}}[a,b] \approx_D P_D^{\text{old}}[a,b].$$

Suppose $d(1), \dots, d(m)$ is the strongest path from alternative b to alternative a in A^{new} .

Case I: Suppose $d(1), \dots, d(m)$ does not contain alternative e . Then $d(1), \dots, d(m)$ was a path from alternative b to alternative a in A^{old} with the same strength. Therefore, we get: $P_D^{\text{old}}[b,a] \approx_D P_D^{\text{new}}[b,a]$.

Case II: Suppose $d(1), \dots, d(m)$ contains alternative e . Suppose $d(s)$ is the last occurrence of alternative e in the path $d(1), \dots, d(m)$. With (2.1.1), (4.16.4), and $d(s) \equiv e$, we get: $(N[b, d(s+1)], N[d(s+1), b]) \approx_D (N[d(s), d(s+1)], N[d(s+1), d(s)])$. So $b, d(s+1), \dots, d(m)$ was a path from alternative b to alternative a in A^{old} of at least the same strength as $d(1), \dots, d(m)$. Therefore, we get: $P_D^{\text{old}}[b,a] \approx_D P_D^{\text{new}}[b,a]$.

So, with Case I and Case II, we get

$$(4.16.7) \quad P_D^{\text{old}}[b,a] \approx_D P_D^{\text{new}}[b,a].$$

With (4.16.6), (4.16.5), and (4.16.7), we get

$$(4.16.8) \quad P_D^{\text{new}}[a,b] \approx_D P_D^{\text{old}}[a,b] \succ_D P_D^{\text{old}}[b,a] \approx_D P_D^{\text{new}}[b,a].$$

With (4.16.8), we get $ab \in O^{\text{new}}$ and, therefore, $b \notin S^{\text{new}}$. □

4.17. Interpolatability

Suppose $\mathcal{LO}_A$ is the set of linear orders on A .

Suppose $\emptyset \neq \mathcal{R} \subseteq \mathcal{LO}_A$ is the set of potential winning rankings for a given election method and a given profile.

An election method is *interpolatable* if, whenever $O_1, O_2 \in \mathcal{LO}_A$ are potential winning rankings of this election method, then also every $O_3 \in \mathcal{LO}_A$ in between must be a potential winning ranking.

Definition:

An election method satisfies *interpolatability* if the following holds for every profile:

$$(4.17.1) \quad \begin{aligned} &\forall O_1, O_2, O_3 \in \mathcal{LO}_A: \\ & (O_1, O_2 \in \mathcal{R} \wedge (O_1 \cap O_2) \subseteq O_3) \Rightarrow (O_3 \in \mathcal{R}). \end{aligned}$$

Claim:

The Schulze method, as defined in section 2.2, satisfies interpolatability.

Proof:

Suppose O_0 is the binary relation defined in (2.2.1). Suppose $O \in \mathcal{LO}_A$. Then, with (2.2.6), we get

$$(4.17.2) \quad O \in \mathcal{R} : \Leftrightarrow O_0 \subseteq O.$$

In section 4.1, it has been proven that the binary relation O_0 , as defined in (2.2.1), is a strict partial order. Therefore, it is guaranteed that $\mathcal{R}$ is not empty. Suppose $O_1, O_2 \in \mathcal{R}$. Then, with (4.17.2), we get

$$(4.17.3) \quad O_0 \subseteq O_1.$$

$$(4.17.4) \quad O_0 \subseteq O_2.$$

With (4.17.3) and (4.17.4), we get

$$(4.17.5) \quad O_0 \subseteq (O_1 \cap O_2).$$

So for $O_3 \in \mathcal{LO}_A$ with $(O_1 \cap O_2) \subseteq O_3$, we get

$$(4.17.6) \quad O_0 \subseteq (O_1 \cap O_2) \subseteq O_3.$$

With (4.17.6), we get

$$(4.17.7) \quad O_0 \subseteq O_3.$$

With (4.17.2) and (4.17.7), we get that also O_3 is a potential winning ranking of the Schulze method. $\square$

Interpolatability is important when we want an election method to respond in a continuous manner to a change of the ballots. Not all election methods are interpolatable. An example for an election method that is not interpolatable is the Kemeny-Young method. This method calculates for every $O \in \mathcal{LO}_A$ the Kemeny score $K(O)$:

$$(4.17.8) \quad K(O) := \sum (N[a,b] - N[b,a] \mid ab \in O).$$

The potential winning rankings of the Kemeny-Young method are the linear orders $O \in \mathcal{LO}_A$ with maximum Kemeny score $K(O)$. The potential winners of the Kemeny-Young method are the top-ranked alternatives of the linear orders $O \in \mathcal{LO}_A$ with maximum Kemeny score $K(O)$.

Example 4.17.9:

3 voters $a \succ_v c \succ_v b \succ_v d$
8 voters $a \succ_v c \succ_v d \succ_v b$
3 voters $b \succ_v a \succ_v d \succ_v c$
6 voters $c \succ_v b \succ_v d \succ_v a$
6 voters $d \succ_v b \succ_v a \succ_v c$
4 voters $d \succ_v c \succ_v b \succ_v a$

The pairwise matrix N looks as follows:

	$N[*,a]$	$N[*,b]$	$N[*,c]$	$N[*,d]$
$N[a,*]$	---	11	20	14
$N[b,*]$	19	---	9	12
$N[c,*]$	10	21	---	17
$N[d,*]$	16	18	13	---

The following table lists the linear orders $O \in \mathcal{LO}_A$ and their Kemeny scores $K(O)$:

linear order O	Kemeny score $K(O)$
<i>abcd</i>	−14
<i>abdc</i>	−22
<i>acbd</i>	10
<i>acdb</i>	22
<i>adbc</i>	−10
<i>adcb</i>	14
<i>bacd</i>	2
<i>badc</i>	−6
<i>bcad</i>	−18
<i>bcda</i>	−14
<i>bdac</i>	−2
<i>bdca</i>	−22
<i>cabd</i>	−10
<i>cadb</i>	2
<i>cbad</i>	6
<i>cbda</i>	10
<i>cdab</i>	6
<i>cdba</i>	22
<i>dabc</i>	−6
<i>dacb</i>	18
<i>dbac</i>	10
<i>dbca</i>	−10
<i>dcab</i>	−2
<i>dcba</i>	14

In example 4.17.9, the linear orders with maximum Kemeny scores are $O_1 = acdb = \{ab, ac, ad, cb, cd, db\}$ and $O_2 = cdba = \{ba, ca, cb, cd, da, db\}$ each with a Kemeny score of 22. We get $(O_1 \cap O_2) = \{cb, cd, db\}$. However, $O_3 = cadb = \{ab, ad, ca, cb, cd, db\}$ with a Kemeny score of 2 and $O_4 = cdab = \{ab, ca, cb, cd, da, db\}$ with a Kemeny score of 6 are not potential winning rankings although $(O_1 \cap O_2) \subseteq O_3$ and $(O_1 \cap O_2) \subseteq O_4$. So interpolatability is violated. When example 4.17.9 is modified slightly, the result goes abruptly from *acdb* to *cdba* without going through *cadb* and *cdab*.

Tideman’s ranked pairs method works from the strongest to the weakest link. The link xy is locked if and only if it doesn’t create a directed cycle with already locked links. Otherwise, this link is locked in its opposite direction (Tideman, 1987).

Example 4.17.10:

1 voter	$a \succ_v c \succ_v d \succ_v b$
5 voters	$a \succ_v d \succ_v b \succ_v c$
2 voters	$a \succ_v d \succ_v c \succ_v b$
4 voters	$b \succ_v a \succ_v c \succ_v d$
3 voters	$c \succ_v b \succ_v a \succ_v d$
5 voters	$c \succ_v d \succ_v b \succ_v a$
3 voters	$d \succ_v c \succ_v b \succ_v a$

The pairwise matrix N looks as follows:

	$N[*,a]$	$N[*,b]$	$N[*,c]$	$N[*,d]$
$N[a,*]$	---	8	12	15
$N[b,*]$	15	---	9	7
$N[c,*]$	11	14	---	13
$N[d,*]$	8	16	10	---

In example 4.17.10, two links have the same strength: ad and ba .

When the ranked pairs method chooses the link ad over the link ba , then it proceeds as follows: It locks db (with a strength of 16:7). Then, it locks ad (with a strength of 15:8). Then it locks ab , since locking ba in its original direction would create a directed cycle with the already locked links ad and db . Then it locks cb (with a strength of 14:9). Then it locks cd (with a strength of 13:10). Then it locks ac (with a strength of 12:11). So the winning ranking is $O_1 = acdb$.

When the ranked pairs method chooses the link ba over the link ad , then it proceeds as follows: It locks db (with a strength of 16:7). Then, it locks ba (with a strength of 15:8). Then it locks da , since locking ad in its original direction would create a directed cycle with the already locked links db and ba . Then it locks cb (with a strength of 14:9). Then it locks cd (with a strength of 13:10). Then it locks ca , since locking ac in its original direction would create a directed cycle with the already locked links cb and ba . So the winning ranking is $O_2 = cdba$.

So the potential winning rankings of the ranked pairs method in example 4.17.10 are $O_1 = acdb = \{ab, ac, ad, cb, cd, db\}$ and $O_2 = cdba = \{ba, ca, cb, cd, da, db\}$. We get $(O_1 \cap O_2) = \{cb, cd, db\}$. However, $O_3 = cadb = \{ab, ad, ca, cb, cd, db\}$ and $O_4 = cdab = \{ab, ca, cb, cd, da, db\}$ are not potential winning rankings although $(O_1 \cap O_2) \subseteq O_3$ and $(O_1 \cap O_2) \subseteq O_4$. So interpolatability is violated. When example 4.17.10 is modified slightly, the result goes abruptly from $acdb$ to $cdab$ without going through $cadb$ and $cdab$.

4.18. Reversal Cancellation

Reversal cancellation says that adding a ballot and its reverse should not change the result of the elections. In other words, a ballot and its reverse should always cancel each other out.

Definition:

Suppose w_1 and w_2 are strict weak orders with

$$(4.18.1) \quad \forall a, b \in A: a \succ_{w_1} b \Leftrightarrow b \succ_{w_2} a.$$

Suppose $V^{\text{new}} := V^{\text{old}} + \{w_1\} + \{w_2\}$.

Then, an election method satisfies *reversal cancellation* if the following holds:

$$(4.18.2) \quad O^{\text{new}} = O^{\text{old}}.$$

$$(4.18.3) \quad S^{\text{new}} = S^{\text{old}}.$$

Claim:

If $\succ_{\text{margin}}$ is being used, then the Schulze method, as defined in section 2.2, satisfies reversal cancellation.

Proof:

The proof is trivial. When w_1 and w_2 , as defined in (4.18.1), are added, then $N^{\text{new}}[a, b] - N^{\text{new}}[b, a] = N^{\text{old}}[a, b] - N^{\text{old}}[b, a]$ for all $a, b \in A$. Therefore

$$(4.18.4) \quad \begin{aligned} & \forall (e, f), (g, h) \in A \times A: \\ & ((N^{\text{new}}[e, f] - N^{\text{new}}[f, e] > N^{\text{new}}[g, h] - N^{\text{new}}[h, g]) \\ & \Leftrightarrow (N^{\text{old}}[e, f] - N^{\text{old}}[f, e] > N^{\text{old}}[g, h] - N^{\text{old}}[h, g])). \end{aligned}$$

Therefore

$$(4.18.5) \quad \begin{aligned} & \forall (e, f), (g, h) \in A \times A: \\ & (N^{\text{new}}[e, f], N^{\text{new}}[f, e]) \succ_{\text{margin}} (N^{\text{new}}[g, h], N^{\text{new}}[h, g]) \\ & \Leftrightarrow (N^{\text{old}}[e, f], N^{\text{old}}[f, e]) \succ_{\text{margin}} (N^{\text{old}}[g, h], N^{\text{old}}[h, g]). \end{aligned}$$

With (2.2.1), (2.2.2), and (4.18.5), we get (4.18.2) and (4.18.3). $\square$

4.19. Woodall’s Plurality Criterion

Woodall’s plurality criterion says: “If some candidate b has strictly fewer votes in total than some other candidate a has first-preference votes, then candidate b should not be elected” (Woodall, 1994, 1996, 1997).

Definition:

Suppose

$$(4.19.1) \quad R_{first}[a] := \left\| \{ v \in V \mid \forall c \in A \setminus \{a\}: a \succ_v c \} \right\|$$

is the number of voters who strictly prefer alternative $a \in A$ to every other alternative (“first-preference votes”).

Suppose

$$(4.19.2) \quad R_{total}[b] := \left\| \{ v \in V \mid \exists c \in A \setminus \{b\}: b \succ_v c \} \right\|$$

is the number of voters who strictly prefer alternative $b \in A$ to at least one other alternative (“votes in total”).

Suppose

$$(4.19.3) \quad R_{first}[a] > R_{total}[b].$$

Then, an election method satisfies *Woodall’s plurality criterion* if the following holds:

$$(4.19.4) \quad ab \in O.$$

$$(4.19.5) \quad b \notin S.$$

Claim:

If $\succ_{win}$ or $\succ_{los}$ is being used, then the Schulze method satisfies Woodall’s plurality criterion.

Proof:

Suppose $a, b \in A$ with (4.19.1) – (4.19.3).

With (4.19.1), we get

$$(4.19.6) \quad \forall c \in A \setminus \{a\}: N[a, c] \geq R_{first}[a].$$

Especially, we get

$$(4.19.7) \quad N[a, b] \geq R_{first}[a].$$

With (4.19.2), we get

$$(4.19.8) \quad \forall c \in A \setminus \{b\}: N[b, c] \leq R_{total}[b].$$

Especially, we get

$$(4.19.9) \quad N[b, a] \leq R_{total}[b].$$

$\succ_{win}$ and $\succ_{los}$ each satisfy (2.1.1).

With (2.1.1), (4.19.7), and (4.19.9), we get

$$(4.19.10) \quad (N[a, b], N[b, a]) \approx_D (R_{first}[a], R_{total}[b]).$$

With (2.2.3) and (4.19.10), we get

$$(4.19.11) \quad P_D[a, b] \approx_D (N[a, b], N[b, a]) \approx_D (R_{first}[a], R_{total}[b]).$$

Case I: Suppose $\succ_{win}$ is used.

With (4.19.3) and with the definition for $\succ_{win}$, we get

$$(4.19.12a) \quad (R_{first}[a], R_{total}[b]) \succ_{win} (R_{total}[b], 0).$$

With (4.19.8) and with the definition for $\succ_{win}$, we get

$$(4.19.13a) \quad \forall c \in A \setminus \{b\}: (N[b, c], N[c, b]) \preceq_{win} (R_{total}[b], 0).$$

Suppose, bd is the first link in the strongest path from alternative b to alternative a . Then, with (4.19.13a), we get

$$(4.19.14a) \quad P_{win}[b, a] \preceq_{win} (N[b, d], N[d, b]) \preceq_{win} (R_{total}[b], 0).$$

With (4.19.11), (4.19.12a), and (4.19.14a), we get

$$(4.19.15a) \quad P_{win}[a, b] \succeq_{win} (R_{first}[a], R_{total}[b]) \succ_{win} (R_{total}[b], 0) \succeq_{win} P_{win}[b, a].$$

With (4.19.15a), we get (4.19.4) and (4.19.5).

Case II: Suppose $\succ_{los}$ is used.

With (4.19.3) and with the definition for $\succ_{los}$, we get

$$(4.19.12b) \quad (R_{first}[a], R_{total}[b]) \succ_{los} (N, R_{first}[a]).$$

With (4.19.6) and with the definition for $\succ_{los}$, we get

$$(4.19.13b) \quad \forall c \in A \setminus \{a\}: (N[c, a], N[a, c]) \preceq_{los} (N, R_{first}[a]).$$

Suppose, da is the last link in the strongest path from alternative b to alternative a . Then, with (4.19.13b), we get

$$(4.19.14b) \quad P_{los}[b, a] \preceq_{los} (N[d, a], N[a, d]) \preceq_{los} (N, R_{first}[a]).$$

With (4.19.11), (4.19.12b), and (4.19.14b), we get

$$(4.19.15b) \quad P_{los}[a, b] \succeq_{los} (R_{first}[a], R_{total}[b]) \succ_{los} (N, R_{first}[a]) \succeq_{los} P_{los}[b, a].$$

With (4.19.15b), we get (4.19.4) and (4.19.5). $\square$

4.20. Perturbation

Perturbation says that alternative $a \in A$ is a potential winner if and only if it is sufficient to add a voter with infinitesimally small weight $\varepsilon \rightarrow 0$ to turn alternative a into a unique winner. In other words: The potential winners are all those alternatives that are unique winners in a perturbed scenario of the original situation.

Claim:

If $>_{\text{margin}}$ is being used, then the Schulze method satisfies perturbation.

Proof:

Claim #1: If alternative $a \in A$ is a potential winner, then it is sufficient to add a voter with infinitesimally small weight $\varepsilon \rightarrow 0$ to turn alternative a into a unique winner.

Proof: $>_{\text{margin}}$ satisfies (2.1.3). Therefore, the Schulze method with $>_{\text{margin}}$ satisfies homogeneity.

$>_{\text{margin}}$ satisfies (2.1.1). Therefore, the Schulze method with $>_{\text{margin}}$ satisfies resolvability, as defined in section 4.3.

The fact that Schulze method with $>_{\text{margin}}$ satisfies claim #1 follows directly from the fact that it satisfies homogeneity and resolvability.

Claim #2: If alternative $a \in A$ it not a potential winner, then it is not sufficient to add a voter with infinitesimally small weight $\varepsilon \rightarrow 0$ to turn alternative a into a unique winner.

Proof: The proof makes use of the fact that, for all $a, b = 1, \dots, C$, $P_{\text{margin}}[a, b]$ is continuous in $N[i, j]$ for all $i, j = 1, \dots, C$. When a voter with weight ε is added, then $N[i, j]$ increases by ε at most, $N[i, j] - N[j, i]$ increases or decreases by ε at most, and $P_{\text{margin}}[i, j]$ increases or decreases by ε at most for all $i, j = 1, \dots, C$.

Suppose $a \in A$ it not a potential winner. Then there is an alternative $b \in A \setminus \{a\}$ with $P_{\text{margin}}^{\text{old}}[a, b] <_{\text{margin}} P_{\text{margin}}^{\text{old}}[b, a]$. $P_{\text{margin}}^{\text{old}}[a, b]$ and $P_{\text{margin}}^{\text{old}}[b, a]$ differ by at least 1 vote. When a voter with infinitesimally small weight $\varepsilon \rightarrow 0$ is added, then $P_{\text{margin}}^{\text{old}}[a, b]$ increases by $\varepsilon \rightarrow 0$ at best and $P_{\text{margin}}^{\text{old}}[b, a]$ decreases by $\varepsilon \rightarrow 0$ at best. Therefore, we still have: $P_{\text{margin}}^{\text{new}}[a, b] <_{\text{margin}} P_{\text{margin}}^{\text{new}}[b, a]$ for $\varepsilon < 0.5$. $\square$

4.21. Munger’s Scenario

In Munger’s scenario, alternative a is identified as best alternative and alternative b is identified as second best alternative. But when alternative a is removed, then alternative b is identified as worst alternative. Munger (2023c) writes: “If the order of candidates is to have something to do with merit, then if the candidate who placed first had not run, then the candidate who placed second should have won. Kemeny-Young and Ranked Pairs have that property, but Beatpath fails it in the worst possible way; the candidate who placed second can become ranked *last* of the remaining candidates.” However, we will prove that Munger’s scenario is not possible under the Schulze method, so that Munger’s criticism doesn’t work. The full correspondence is here: Munger (2023a) $\rightarrow$ Munger (2023b) $\rightarrow$ Munger (2023c) $\rightarrow$ Schulze (2024b) $\rightarrow$ Munger (2024a) $\rightarrow$ Munger (2024b) $\rightarrow$ Munger (2024c).

As the Schulze method satisfies decisiveness (section 4.2), there is usually a unique winner. As the Schulze method satisfies decisiveness (section 4.2) and reversal symmetry (section 4.5), there is usually a unique worst alternative. However, the Schulze method usually doesn’t find a unique linear order of all alternatives (section 3.5). Therefore, the term “second best” is open to interpretation. I presume that, when alternative $a \in A$ is identified as best alternative, then the term “second best” refers to every alternative $b \in A \setminus \{a\}$ that is disqualified only by alternative a .

Claim:

Suppose there were at least 3 alternatives in the original situation. Suppose $\succ_D$ satisfies (2.1.5). Then Munger’s scenario is not possible under the Schulze method.

Proof:

We will presume that alternative $a \in A$ was a unique winner, that alternative $b \in A \setminus \{a\}$ was a second best alternative and that, when alternative a is removed, then alternative b becomes a unique worst alternative. We will show that these presumptions ultimately lead to contradictions (step 4).

Step 1:

Suppose alternative a was the unique winner in the original situation. Then, with (4.1.15), we get:

$$(4.21.1) \quad \forall x \in A \setminus \{a\}: P_D^{\text{old}}[a, x] \succ_D P_D^{\text{old}}[x, a].$$

Suppose alternative b was a second best alternative in the original situation. Then we get:

$$(4.21.2) \quad \forall x \in A \setminus \{a, b\}: P_D^{\text{old}}[b, x] \approx_D P_D^{\text{old}}[x, b].$$

Suppose alternative b is the unique worst alternative when alternative a is removed. Then we get:

$$(4.21.3) \quad \forall x \in A \setminus \{a, b\}: P_D^{\text{new}}[x, b] \succ_D P_D^{\text{new}}[b, x].$$

When alternative a is removed, then the strength of the strongest path from alternative $x \in A \setminus \{a\}$ to alternative $y \in A \setminus \{a, x\}$ either decreases or stays the same. But $P_D[x, y]$ cannot increase, since the set of possible paths is only reduced. Therefore, we get:

$$(4.21.4) \quad \forall x \in A \setminus \{a, b\}: P_D^{\text{old}}[x, b] \approx_D P_D^{\text{new}}[x, b].$$

With (4.21.2), (4.21.4) and (4.21.3), we get:

$$(4.21.5) \quad \forall x \in A \setminus \{a, b\}: P_D^{\text{old}}[b, x] >_D P_D^{\text{new}}[b, x].$$

But (4.21.5) is possible only when, for every $x \in A \setminus \{a, b\}$, alternative a was in every strongest path from alternative b to alternative x .

Step 2:

Without loss of generality, we can assume that the Floyd-Warshall algorithm is used to calculate the strongest paths (as defined in section 2.3.1). The strongest paths then have the property that every sub-sequence is also a strongest path. So when the sequence $c(1), \dots, c(n)$ is a strongest path from alternative $c(1)$ to alternative $c(n)$ then, for every $1 \leq i < j \leq n$, the sub-sequence $c(i), \dots, c(j)$ is a strongest path from alternative $c(i)$ to alternative $c(j)$.

Suppose there were alternatives $x_1, x_2 \in A \setminus \{a, b\}$ such that the link bx_1 was the first link in the strongest path from alternative b to alternative x_2 . Then already the link bx_1 was a strongest path from alternative b to alternative x_1 . But this is a contradiction to the result of step 1 that, for every $x_1 \in A \setminus \{a, b\}$, alternative a was in every strongest path from alternative b to alternative x_1 . Therefore, without loss of generality, we can assume (1) that, for every $x \in A \setminus \{a, b\}$, the link ba was the first link in every strongest path from alternative b to alternative x and (2) that the unique strongest path from alternative b to alternative a was the link ba .

Step 3:

Suppose ax_3 with $x_3 \in A \setminus \{a, b\}$ was the first link in the strongest path from alternative a to alternative b . Then, with the result of step 2, we get that the strongest paths must have had the following structure:

With (4.21.1), we get $P_D^{\text{old}}[a,b] \succ_D P_D^{\text{old}}[b,a]$ and therefore:

$$(4.21.6) \quad \min_D \{ (N[a,x_3], N[x_3,a]), P_D^{\text{old}}[x_3,b] \} \succ_D (N[b,a], N[a,b])$$

and therefore:

$$(4.21.7) \quad P_D^{\text{old}}[x_3,b] \succ_D (N[b,a], N[a,b]).$$

With (4.21.2), we get $P_D^{\text{old}}[b,x_3] \approx_D P_D^{\text{old}}[x_3,b]$ and therefore:

$$(4.21.8) \quad \min_D \{ (N[b,a], N[a,b]), (N[a,x_3], N[x_3,a]) \} \approx_D P_D^{\text{old}}[x_3,b]$$

and therefore:

$$(4.21.9) \quad (N[b,a], N[a,b]) \approx_D P_D^{\text{old}}[x_3,b].$$

But (4.21.7) and (4.21.9) are incompatible. Therefore, it is not possible that the link ax_3 with some alternative $x_3 \in A \setminus \{a,b\}$ was the first link in the strongest path from alternative a to alternative b . Therefore, the strongest path from alternative a to alternative b must have been the link ab .

Step 4:

So in step 2, we have seen that the strongest path from alternative b to alternative a was the link ba . And in step 3, we have seen that the strongest path from alternative a to alternative b was the link ab .

Therefore, we get:

$$(4.21.10) \quad P_D^{\text{old}}[b,a] \approx_D (N[b,a], N[a,b]).$$

$$(4.21.11) \quad P_D^{\text{old}}[a,b] \approx_D (N[a,b], N[b,a]).$$

Case I: Suppose

$$(4.21.12) \quad N[a,b] \leq N[b,a].$$

With (2.1.5) and (4.21.12), we get:

$$(4.21.13) \quad (N[a,b], N[b,a]) \preceq_D (N[b,a], N[a,b]).$$

With (4.21.11), (4.21.13) and (4.21.10), we get:

$$(4.21.14) \quad P_D^{\text{old}}[a,b] \preceq_D P_D^{\text{old}}[b,a].$$

But (4.21.14) contradicts (4.21.1).

Case II: Suppose

$$(4.21.15) \quad N[a,b] > N[b,a].$$

Suppose $c \in A \setminus \{a,b\}$. Such an alternative exists, as we had presumed that there were at least 3 alternatives in the original situation.

Case IIa: Suppose

$$(4.21.16) \quad N[b,c] \geq N[c,b].$$

Then, with (2.1.5), (4.21.15) and (4.21.16), we get:

$$(4.21.17) \quad (N[b,c], N[c,b]) >_D (N[b,a], N[a,b]).$$

So already the link bc was a stronger path from alternative b to alternative c than every path that starts with the link ba . But this contradicts the observation in step 2 that, for every $x \in A \setminus \{a,b\}$, the link ba was the first link in every strongest path from alternative b to alternative x .

Case IIb: Suppose

$$(4.21.18) \quad N[b,c] < N[c,b].$$

Then, with (2.1.5), (4.21.15) and (4.21.18), we get:

$$(4.21.19) \quad (N[c,b], N[b,c]) >_D (N[b,a], N[a,b]).$$

With (4.21.19) and the observation in step 2 that, for every $x \in A \setminus \{a,b\}$, the link ba was the first link in every strongest path from alternative b to alternative x , we get that the link cb was already a stronger path from alternative c to alternative b than every path from alternative b to alternative c . But this contradicts (4.21.2). $\square$

The fact, that Munger’s scenario isn’t possible under the Schulze method, also means that it isn’t possible that the collective ranking of the remaining alternatives is reversed when the best alternative is removed (since reversing the collective ranking would imply that the second best alternative of the original situation becomes the worst in the new situation).

The proof that, when the worst alternative is removed, the second worst alternative of the original situation cannot become the best alternative in the new situation is equivalent to the proof that Munger’s scenario isn’t possible under the Schulze method.

So the fact that Munger’s scenario isn’t possible under the Schulze method basically means that removing the best or the worst alternative cannot reverse the collective ranking of the remaining alternatives.

5. Tie-Breaking

In this section, we will propose a more elaborate definition for the Schulze method. This more elaborate version addresses 3 problems of the simpler definition of section 2.2.

Problem #1: It can happen that the weakest link in the strongest path from alternative a to alternative b and the weakest link in the strongest path from alternative b to alternative a are the same link, say cd . In this case, the Schulze method is indifferent between alternative a and alternative b , i.e. $ab \notin O$ and $ba \notin O$. See sections 3.5, 3.11, 3.12, and 4.2.

We recommend that, to resolve this indifference, the link cd should be declared *forbidden* and the strongest paths from alternative a to alternative b and from alternative b to alternative a , that don’t contain *forbidden* links, should be calculated. Either this indifference is now resolved or, again, the weakest link in the strongest path from alternative a to alternative b and the weakest link in the strongest path from alternative b to alternative a are the same link, say ef . In the latter case, the link ef is declared *forbidden* and the strongest paths that don’t contain *forbidden* links are calculated. This procedure is repeated until this indifference is resolved. The resulting Schulze relation will be called O_{final} .

In example 5 (section 3.5), the link cd is the weakest link in the strongest path from alternative a to alternative b and the weakest link in the strongest path from alternative b to alternative a . Therefore, the link cd is declared *forbidden*. The strongest path from alternative a to alternative b , that doesn’t contain *forbidden* links, is $a,(33,30),b$. The strongest path from alternative b to alternative a , that doesn’t contain *forbidden* links, is $b,(30,33),a$. Therefore, we get $ab \in O_{final}$.

Problem #2: We want the Schulze method to satisfy *composition consistency*. That means: When $\emptyset \neq K \subsetneq A$ is a set of clones, as defined in (4.7.1) – (4.7.3), then, when we apply the election method only to the alternatives in K , the result should be the same as if we had applied the election method to A and then looked only at the alternatives in K . See (4.7.9) – (4.7.13) and (5.3.6.8) – (5.3.6.10). See also Öztürk (2020) and Berker (2025).

The simpler definition for the Schulze method in section 2.2 violates composition consistency because it can happen that the strongest path from $g \in K$ to $h \in K \setminus \{g\}$ passes through alternatives $a, b \in A \setminus K$.

As $\emptyset \neq K \subsetneq A$ is a set of clones, we get $(N[g,a], N[a,g]) \approx_D (N[h,a], N[a,h])$ and $(N[b,g], N[g,b]) \approx_D (N[b,h], N[h,b])$ for all $g, h \in K$ and for all $a, b \in A \setminus K$. Therefore, we get:

When $g, (N[g,a], N[a,g]), a, P_\sigma[a,b], b, (N[b,h], N[h,b]), h$ is the strongest path from alternative g to alternative h , then $h, (N[h,a], N[a,h]), a, P_\sigma[a,b], b, (N[b,g], N[g,b]), g$ is the strongest path from alternative h to alternative g .

When the strongest path from $g \in K$ to $h \in K \setminus \{g\}$ passes through alternatives $a, b \in A \setminus K$, there are three possible cases:

(i) The weakest link in the strongest path from g to h could be the weakest link in the strongest path from a to b . As the sequence $a, P_\sigma[a,b], b$ is in the strongest path from g to h and simultaneously in the strongest path from h to g , this means that the weakest link in the strongest path from g to h is the same link as the weakest link in the strongest path from h to g . However, this case has already been addressed in problem #1.

(ii) The weakest link in the strongest path from g to h could be the link ga . In this case, ga with $(N[g,a], N[a,g]) \approx_D (N[h,a], N[a,h])$ is the weakest link in the strongest path from h to g . In this case, we recommend that $\mathcal{O}_K$ should be calculated and that, when $gh \in \mathcal{O}_K$, we arbitrarily set $(N[g,a], N[a,g]) >_D (N[h,a], N[a,h])$, so that the weakest link in the strongest path from g to h arbitrarily becomes stronger than the weakest link in the strongest path from h to g so that $gh \in \mathcal{O}$. See section 5.1 step 2 (b) (1).

(iii) The weakest link in the strongest path from g to h could be the link bh . In this case, bh with $(N[b,g], N[g,b]) \approx_D (N[b,h], N[h,b])$ is the weakest link in the strongest path from h to g . In this case, we recommend that $\mathcal{O}_K$ should be calculated and that, when $gh \in \mathcal{O}_K$, we arbitrarily set $(N[b,g], N[g,b]) <_D (N[b,h], N[h,b])$, so that the weakest link in the strongest path from g to h arbitrarily becomes stronger than the weakest link in the strongest path from h to g so that $gh \in \mathcal{O}$. See section 5.1 step 2 (b) (2).

Problem #3: We want to know how to choose the final winner from among the potential winners when the simpler definition for the Schulze method finds more than one potential winner. We want to solve these situations without having to sacrifice any of the desirable properties of the Schulze method.

To solve these situations, we recommend that a Tie-Breaking Ranking of the Voters (TBRV) and a Tie-Breaking Ranking of the Candidates (TBRC) should be calculated and that indecisive situations should be perturbed in favour of those voters who are ranked higher in this TBRV resp. in favour of those alternatives that are ranked higher in this TBRC.

5.1. Calculating a Complete Ranking Using a Tie-Breaking Ranking of the Links

The Schulze relation O , as defined in (2.2.1), is only a strict partial order. However, sometimes, a linear order is needed. In this section, we will show how the Schulze relation O can be completed to a linear order $O_{final}(\sigma)$ without having to sacrifice any of the desired criteria. The following four steps describe how the linear order $O_{final}(\sigma)$ is calculated.

Step 1 (calculating a TBRV $\succ_\xi$ and a first TBRC $\succ_\omega$):

A *Tie-Breaking Ranking of the Voters* (TBRV), a linear order $\succ_\xi$ on V , is calculated by ranking the voters in V randomly.

A first *Tie-Breaking Ranking of the Candidates* (TBRC), a linear order $\succ_\omega$ on A , is calculated by ranking the alternatives in A randomly.

When the bylaws require that the chairperson decides in the case of a tie, then, for the calculation of the TBRV, the chairperson has to be chosen first.

Step 2 (calculating a TBRL $\succ_\sigma$ and a second TBRC $\succ_\mu$):

We now use the TBRV $\succ_\xi$ and the first TBRC $\succ_\omega$ to calculate a *Tie-Breaking Ranking of the Links* (TBRL), a linear order $\succ_\sigma$ on $A \times A$, and a second TBRC $\succ_\mu$. The second TBRC $\succ_\mu$ is only needed to complete the TBRL $\succ_\sigma$. So the final result $O_{final}(\sigma)$ depends only on $\succ_\sigma$.

(a) We start with:

- $\forall (i,j),(m,n) \in A \times A: (N[i,j], N[j,i]) \succ_D (N[m,n], N[n,m]) \Rightarrow ij \succ_\sigma mn.$
- $\forall (i,j),(m,n) \in A \times A: (N[i,j], N[j,i]) \approx_D (N[m,n], N[n,m]) \Rightarrow ij \approx_\sigma mn.$
- $\forall i,j \in A: i \approx_\mu j.$

(b) (1) It can happen (e.g. when there are clones) that there are links with equivalent strengths and the same ending alternative: $ij \approx_D mj$.

In these cases, we determine $K(i,j) := \{ k \in A \mid kj \approx_D ij \}$. If $\| K(i,j) \| > 1$, then (before we calculate $O_{final}(\sigma)$ for A as defined in stages 3 and 4) we first calculate $\psi := \sigma|_{K(i,j)}$ and $O_{final}(\psi)|_{K(i,j)}$ and then we set: If $mn \in O_{final}(\psi)|_{K(i,j)}$ then $mj \succ_\sigma nj$.

(2) It can happen (e.g. when there are clones) that there are links with equivalent strengths and the same starting alternative: $ij \approx_D im$.

In these cases, we determine $L(i,j) := \{ k \in A \mid ik \approx_D ij \}$. If $\| L(i,j) \| > 1$, then (before we calculate $O_{final}(\sigma)$ for A as defined in stages 3 and 4) we first calculate $\psi := \sigma|_{L(i,j)}$ and $O_{final}(\psi)|_{L(i,j)}$ and then we set: If $mn \in O_{final}(\psi)|_{L(i,j)}$, then $in \succ_\sigma im$.

(3) It can happen that $K(i,j)$ or $L(i,j)$ contains links with equivalent strengths and the same starting alternative or the same ending alternative. In these cases, we first calculate $\psi := \sigma|_{\mathcal{K}(m,n)}$ resp. $\psi := \sigma|_{\mathcal{L}(m,n)}$ and $O_{final}(\psi)|_{\mathcal{K}(m,n)}$ resp. $O_{final}(\psi)|_{\mathcal{L}(m,n)}$ for $\mathcal{K}(m,n) := \{ k \in K(i,j) \mid kn \approx_D mn \}$ resp. $\mathcal{K}(m,n) := \{ k \in L(i,j) \mid kn \approx_D mn \}$ and $\mathcal{L}(m,n) := \{ k \in K(i,j) \mid mk \approx_D mn \}$ resp. $\mathcal{L}(m,n) := \{ k \in L(i,j) \mid mk \approx_D mn \}$. If $st \in O_{final}(\psi)|_{\mathcal{K}(m,n)}$ then we set: $sn \succ_{\sigma|_{K(i,j)}} tn$ resp. $sn \succ_{\sigma|_{L(i,j)}} tn$. If $st \in O_{final}(\psi)|_{\mathcal{L}(m,n)}$, then we set: $mt \succ_{\sigma|_{K(i,j)}} ms$ resp. $mt \succ_{\sigma|_{L(i,j)}} ms$. We proceed until there are no links anymore with equivalent strengths and the same starting alternative or the same ending alternative.

(c) From the first voter to the last voter, according to $>_{\xi}$, we use his ranking to complete $>_{\sigma}$. Suppose $v \in V$ is the current voter. Then we proceed:

Step 1: $\forall i, j \in A$: If $i \approx_{\mu} j$ and $i >_v j$, then replace " $i \approx_{\mu} j$ " by " $i >_{\mu} j$ ".

Step 2: $\forall (i, j), (m, n) \in A \times A$:

If $ij \approx_{\sigma} mn$ and

$$(5.1.1) \quad ((i \approx_v j) \wedge (m <_v n)) \vee ((i >_v j) \wedge (m \approx_v n)),$$

then replace " $ij \approx_{\sigma} mn$ " by " $ij >_{\sigma} mn$ ".

Step 3: It can happen, that $>_{\sigma}$ contains a directed cycle. In this case, we replace all $>_{\sigma}$ of this directed cycle (except for those that had already been locked before we used the ranking of voter $v \in V$) by $\approx_{\sigma}$.

Step 4: $>_{\sigma}$ is updated to its transitive closure.

(d) If you go through all ballots and there are still alternatives $i, j \in A$ with $i \approx_{\mu} j$, then proceed as follows: If $i \approx_{\mu} j$ and $i >_{\omega} j$, then replace " $i \approx_{\mu} j$ " by " $i >_{\mu} j$ ".

(e) Suppose there are still $(i, j), (m, n) \in A \times A$ with $ij \approx_{\sigma} mn$, then proceed as follows:

Variant 1: When at least one of the following conditions is satisfied, then replace " $ij \approx_{\sigma} mn$ " by " $ij >_{\sigma} mn$ ":

- (5.1.2a) $i >_{\mu} j$ and $n >_{\mu} m$.
- (5.1.3a) $i >_{\mu} j$ and $m >_{\mu} n$ and $i >_{\mu} m$.
- (5.1.4a) $j >_{\mu} i$ and $n >_{\mu} m$ and $n >_{\mu} j$.
- (5.1.5a) $i \equiv m$ and $n >_{\mu} j$.
- (5.1.6a) $j \equiv n$ and $i >_{\mu} m$.

Variant 2: When at least one of the following conditions is satisfied, then replace " $ij \approx_{\sigma} mn$ " by " $ij >_{\sigma} mn$ ":

- (5.1.2b) $i >_{\mu} j$ and $n >_{\mu} m$.
- (5.1.3b) $i >_{\mu} j$ and $m >_{\mu} n$ and $n >_{\mu} j$.
- (5.1.4b) $j >_{\mu} i$ and $n >_{\mu} m$ and $i >_{\mu} m$.
- (5.1.5b) $i \equiv m$ and $n >_{\mu} j$.
- (5.1.6b) $j \equiv n$ and $i >_{\mu} m$.

(5.1.2a) – (5.1.6a) and (5.1.2b) – (5.1.6b) are chosen in such a manner that e.g. when the TBRC $>_{\mu}$ is $abcdefgh$ then links of otherwise equivalent strengths are sorted $ah, ag, af, ae, ad, ac, ab, bh, bg, bf, be, bd, bc, ch, cg, cf, ce, cd, dh, dg, df, de, eh, eg, ef, fh, fg, gh, hg, gf, hf, fe, ge, he, ed, fd, gd, hd, dc, ec, fc, gc, hc, cb, db, eb, fb, gb, hb, ba, ca, da, ea, fa, ga, ha$ in variant 1 resp. $ah, bh, ch, dh, eh, fh, gh, ag, bg, cg, dg, eg, fg, af, bf, cf, df, ef, ae, be, ce, de, ad, bd, cd, ac, bc, ab, ba, cb, ca, dc, db, da, ed, ec, eb, ea, fe, fd, fc, fb, fa, gf, ge, gd, gc, gb, ga, hg, hf, he, hd, hc, hb, ha$ in variant 2.

Stage 3 (initializing the strongest paths):

```

1  for  $i := 1$  to  $C$ 
2  begin
3    for  $j := 1$  to  $C$ 
4    begin
5      if (  $i \neq j$  ) then
6        begin
7           $P_o[i,j] := ij$ 
8        end
9      end
10 end

11 for  $i := 1$  to  $C$ 
12 begin
13   for  $j := 1$  to  $C$ 
14   begin
15     if (  $i \neq j$  ) then
16       begin
17         for  $k := 1$  to  $C$ 
18         begin
19           if (  $i \neq k$  ) then
20             begin
21               if (  $j \neq k$  ) then
22                 begin
23                   if (  $P_o[j,k] <_\sigma \min_\sigma \{ P_o[j,i], P_o[i,k] \}$  ) then
24                     begin
25                        $P_o[j,k] := \min_\sigma \{ P_o[j,i], P_o[i,k] \}$ 
26                     end
27                   end
28                 end
29               end
30             end
31           end
32         end

33  $O_{final}(\sigma) := \emptyset$ 
34  $S_{final}(\sigma) := A$ 
35 for  $i := 1$  to  $C$ 
36 begin
37   for  $j := 1$  to  $C$ 
38   begin
39     if (  $i \neq j$  ) then
40       begin
41         if (  $P_o[j,i] >_\sigma P_o[i,j]$  ) then
42           begin
43              $O_{final}(\sigma) := O_{final}(\sigma) + \{ji\}$ 
44              $S_{final}(\sigma) := S_{final}(\sigma) \setminus \{i\}$ 
45           end
46         end
47       end
48     end

```

Stage 4 (applying the TBRL $\succ_\sigma$):

```

49  $xy := \min_\sigma \{ ij \mid ij \in \{1, \dots, C\}, i \neq j \}$ 
50 for  $m := 1$  to  $C-1$ 
51 begin
52   for  $n := m+1$  to  $C$ 
53   begin
54     if (  $P_\sigma[m,n] \approx_\sigma P_\sigma[n,m]$  ) then
55     begin
56        $Q_\sigma[m,n] := P_\sigma[m,n]$ 
57       for  $i := 1$  to  $C$ 
58       begin
59         for  $j := 1$  to  $C$ 
60         begin
61           if (  $i \neq j$  ) then
62           begin
63              $forbidden[i,j] := false$ 
64           end
65         end
66       end
67        $bool1 := false$ 
68       while (  $bool1 = false$  )
69       begin
70         for  $i := 1$  to  $C$ 
71         begin
72           for  $j := 1$  to  $C$ 
73           begin
74             if (  $i \neq j$  ) then
75             begin
76               if (  $Q_\sigma[m,n] \approx_\sigma ij$  ) then
77               begin
78                  $forbidden[i,j] := true$ 
79               end
80             end
81           end
82         end
83       for  $i := 1$  to  $C$ 
84       begin
85         for  $j := 1$  to  $C$ 
86         begin
87           if (  $i \neq j$  ) then
88           begin
89             if (  $forbidden[i,j] = true$  ) then
90             begin
91                $Q_\sigma[i,j] := xy$ 
92             end
93           else
94           begin
95              $Q_\sigma[i,j] := ij$ 
96           end
97         end
98       end
99     end

```

```

100   for  $i : = 1$  to  $C$ 
101   begin
102     for  $j : = 1$  to  $C$ 
103     begin
104       if (  $i \neq j$  ) then
105       begin
106         for  $k : = 1$  to  $C$ 
107         begin
108           if (  $i \neq k$  ) then
109           begin
110             if (  $j \neq k$  ) then
111             begin
112               if (  $Q_\sigma[j,k] <_\sigma \min_\sigma \{ Q_\sigma[j,i], Q_\sigma[i,k] \}$  ) then
113               begin
114                  $Q_\sigma[j,k] := \min_\sigma \{ Q_\sigma[j,i], Q_\sigma[i,k] \}$ 
115               end
116             end
117           end
118         end
119       end
120     end
121   end
122   if (  $Q_\sigma[m,n] >_\sigma Q_\sigma[n,m]$  ) then
123   begin
124      $O_{final}(\sigma) := O_{final}(\sigma) + \{mn\}$ 
125      $S_{final}(\sigma) := S_{final}(\sigma) \setminus \{n\}$ 
126      $bool1 := true$ 
127   end
128   else
129   begin
130     if (  $Q_\sigma[m,n] <_\sigma Q_\sigma[n,m]$  ) then
131     begin
132        $O_{final}(\sigma) := O_{final}(\sigma) + \{nm\}$ 
133        $S_{final}(\sigma) := S_{final}(\sigma) \setminus \{m\}$ 
134        $bool1 := true$ 
135     end
136     else
137       if (  $Q_\sigma[m,n] = xy$  and  $Q_\sigma[n,m] = xy$  ) then
138       begin
139          $bool1 := true$ 
140       end
141     end
142   end
143 end
144 end
145 end

```

For each pair of alternatives $m, n \in A$, we check whether $P_\sigma[m,n] \approx_\sigma P_\sigma[n,m]$ (lines 50–55). In this case, the link ij with $P_\sigma[m,n] \approx_\sigma ij$ is declared *forbidden* (lines 70–82) and the strongest paths, that don't contain *forbidden* links, are calculated (lines 83–121). This procedure is repeated (lines 67–68) until this indifference is resolved (lines 122–135) or all links have been declared *forbidden* (lines 136–140).

Example 5.1.1

Example 5.1.1:

6 voters	$a \succ_v b \succ_v c \succ_v d$
2 voters	$b \succ_v a \succ_v c \succ_v d$
6 voters	$c \succ_v d \succ_v b \succ_v a$
4 voters	$d \succ_v a \succ_v b \succ_v c$
1 voter	$d \succ_v b \succ_v c \succ_v a$

The pairwise matrix N looks as follows:

	$N[*,a]$	$N[*,b]$	$N[*,c]$	$N[*,d]$
$N[a,*]$	---	10	12	8
$N[b,*]$	9	---	13	8
$N[c,*]$	7	6	---	14
$N[d,*]$	11	11	5	---

The corresponding digraph looks as follows:

In section 5.1 step 2 (a), we get:

$$\begin{aligned}
 (N[c,d], N[d,c]) &>_{\sigma} (N[b,c], N[c,b]) >_{\sigma} (N[a,c], N[c,a]) \\
 &>_{\sigma} (N[d,a], N[a,d]) \approx_{\sigma} (N[d,b], N[b,d]) >_{\sigma} (N[a,b], N[b,a]).
 \end{aligned}$$

The links da and db have equivalent strengths and the same start $d \in A$. Therefore, we apply section 5.1 step 2 (b) (2). When we apply the Schulze method only to $\{a, b\}$, we get $a \succ_S b$. Thus, we set $(N[d,b], N[b,d]) >_{\sigma} (N[d,a], N[a,d])$.

When we apply section 5.1 step 3, we finally get $O_{final}(\sigma) = \{ab, ac, ad, bc, bd, cd\}$ and $S_{final}(\sigma) = \{a\}$.

5.2. Transitivity

In section 4.1, we have proven that the binary relation O , as defined in (2.2.1), is transitive. Nevertheless, it isn’t intuitively clear whether also the binary relation $O_{final}(\sigma)$, as defined in section 5.1, is transitive. It seems to be possible that ties $P_\sigma[x,y] \approx_\sigma P_\sigma[y,x]$ are resolved based on different sets of *non-forbidden* links, so that the transitivity of $O_{final}(\sigma)$ doesn’t follow directly from the transitivity of O .

However, in the following proof, we will see that also the binary relation $O_{final}(\sigma)$, as defined in section 5.1, is transitive. We will prove that ties $P_\sigma[x,y] \approx_\sigma P_\sigma[y,x]$ are either resolved based on the same set of *non-forbidden* links (sections 5.2.1, 5.2.4, and 5.2.5) or — in those cases, where these ties happen to be resolved based on different sets of *non-forbidden* links — they cannot violate transitivity (sections 5.2.2 and 5.2.3).

5.2.1. Part 1

Suppose, before we start declaring links *forbidden*, we have:

$$(5.2.1.1) \quad P_\sigma[a,b] >_\sigma P_\sigma[b,a].$$

$$(5.2.1.2) \quad P_\sigma[b,c] >_\sigma P_\sigma[c,b].$$

$$(5.2.1.3) \quad P_\sigma[c,a] \approx_\sigma P_\sigma[a,c].$$

With (5.2.1.1), we get $ab \in O$ and, therefore, $ab \in O_{final}(\sigma)$.

With (5.2.1.2), we get $bc \in O$ and, therefore, $bc \in O_{final}(\sigma)$.

This situation is not possible because, when no link has been declared *forbidden*, then all paths are calculated based on the same set of *non-forbidden* links. But in section 4.1, we have proven that, when all paths are calculated based on the same set of links, then the binary relation O , as defined by $P_\sigma[x,y] >_\sigma P_\sigma[y,x]$, is transitive. So, with $P_\sigma[a,b] >_\sigma P_\sigma[b,a]$ and $P_\sigma[b,c] >_\sigma P_\sigma[c,b]$, we immediately get $P_\sigma[a,c] >_\sigma P_\sigma[c,a]$.

5.2.2. Part 2

Suppose, before we start declaring links *forbidden*, we have:

$$(5.2.2.1) \quad P_\sigma[a,b] <_\sigma P_\sigma[b,a].$$

$$(5.2.2.2) \quad P_\sigma[b,c] >_\sigma P_\sigma[c,b].$$

$$(5.2.2.3) \quad P_\sigma[c,a] \approx_\sigma P_\sigma[a,c].$$

With (5.2.2.1), we get $ba \in O$ and, therefore, $ba \in O_{final}(\sigma)$.

With (5.2.2.2), we get $bc \in O$ and, therefore, $bc \in O_{final}(\sigma)$.

Suppose there are no pairwise links of equivalent strengths. Suppose (5.2.2.1) – (5.2.2.3). With (5.2.2.3), we get that the weakest link in the strongest path from alternative a to alternative c and the weakest link in the strongest path from alternative c to alternative a must be the same link, say de .

Therefore, the strongest paths have the following structure:

In this case, it can actually happen that the paths are based on different sets of *non-forbidden* links. In example 11 (section 3.11), we have a situation with $P_\sigma[a,b] <_\sigma P_\sigma[b,a]$, $P_\sigma[b,c] >_\sigma P_\sigma[c,b]$, and $P_\sigma[c,a] \approx_\sigma P_\sigma[a,c]$ and where the link de is the weakest link in the strongest path from alternative a to alternative c and simultaneously the weakest link in the strongest path from alternative c to alternative a . So when we resolve $P_\sigma[c,a] \approx_\sigma P_\sigma[a,c]$, the link de has to be declared *forbidden*. The strongest path from alternative a to alternative c , that doesn't contain the link de , is $a, (24, 21), c$. The strongest path from alternative c to alternative a , that doesn't contain the link de , is $c, (25, 20), b, (22, 23), e, (30, 15), a$. So $P_\sigma[c,a] \approx_\sigma P_\sigma[a,c]$ is resolved to $ac \in O_{final}(\sigma)$.

Now the interesting observation is that the link de is also in the strongest path from alternative b to alternative a . And the strongest path $b, (22, 23), e, (30, 15), a$ from alternative b to alternative a , that doesn't contain the link de , is weaker than the strongest path $a, (26, 19), b$ from alternative a to alternative b , that doesn't contain the link de . Therefore, if we had to recalculate the strengths of the strongest paths from alternative a to alternative b and from alternative b to alternative a based on the fact that the link de has been declared *forbidden* { what we don't have to do, because each of (5.2.2.1) – (5.2.2.3) is resolved separately, based on its own set of *non-forbidden* links }, we would get $P_\sigma[a,b] >_\sigma P_\sigma[b,a]$.

Furthermore, the link de is in the strongest path from alternative b to alternative c . And the strongest path $b, (22, 23), e, (32, 13), c$ from alternative b to alternative c , that doesn't contain the link de , is weaker than the strongest path $c, (25, 20), b$ from alternative c to alternative b , that doesn't contain the link de . Therefore, if we had to recalculate the strengths of the strongest paths from alternative b to alternative c and from alternative c to alternative b based on the fact that the link de has been declared *forbidden*, we would get $P_\sigma[b,c] <_\sigma P_\sigma[c,b]$.

So example 11 (section 3.11) demonstrates that it can happen that (5.2.2.1) – (5.2.2.3) are resolved based on different sets of *non-forbidden* links. However, this is not a problem because — it doesn't matter whether $P_\sigma[c,a] \approx_\sigma P_\sigma[a,c]$ is resolved to $P_\sigma[c,a] >_\sigma P_\sigma[a,c]$ or to $P_\sigma[c,a] <_\sigma P_\sigma[a,c]$ — transitivity will never be violated.

5.2.3. Part 3

Suppose, before we start declaring links *forbidden*, we have:

$$(5.2.3.1) \quad P_{\sigma}[a,b] >_{\sigma} P_{\sigma}[b,a].$$

$$(5.2.3.2) \quad P_{\sigma}[b,c] <_{\sigma} P_{\sigma}[c,b].$$

$$(5.2.3.3) \quad P_{\sigma}[c,a] \approx_{\sigma} P_{\sigma}[a,c].$$

With (5.2.3.1), we get $ab \in O$ and, therefore, $ab \in O_{final}(\sigma)$.

With (5.2.3.2), we get $cb \in O$ and, therefore, $cb \in O_{final}(\sigma)$.

Suppose there are no pairwise links of equivalent strengths. Suppose (5.2.3.1) – (5.2.3.3). With (5.2.3.3), we get that the weakest link in the strongest path from alternative a to alternative c and the weakest link in the strongest path from alternative c to alternative a must be the same link, say de .

Therefore, the strongest paths have the following structure:

In this case, it can actually happen that the paths are based on different sets of *non-forbidden* links. In example 12 (section 3.12), we have a situation with $P_{\sigma}[a,b] >_{\sigma} P_{\sigma}[b,a]$, $P_{\sigma}[b,c] <_{\sigma} P_{\sigma}[c,b]$, and $P_{\sigma}[c,a] \approx_{\sigma} P_{\sigma}[a,c]$ and where the link de is the weakest link in the strongest path from alternative a to alternative c and simultaneously the weakest link in the strongest path from alternative c to alternative a . So when we resolve $P_{\sigma}[c,a] \approx_{\sigma} P_{\sigma}[a,c]$, the link de has to be declared *forbidden*. The strongest path from alternative a to alternative c , that doesn't contain the link de , is $a, (24,21), c$. The strongest path from alternative c to alternative a , that doesn't contain the link de , is $c, (30,15), d, (22,23), b, (25,20), a$. So $P_{\sigma}[c,a] \approx_{\sigma} P_{\sigma}[a,c]$ is resolved to $ac \in O_{final}(\sigma)$.

Now the interesting observation is that the link de is also in the strongest path from alternative a to alternative b . And the strongest path $a, (32,13), d, (22,23), b$ from alternative a to alternative b , that doesn't contain the link de , is weaker than the strongest path $b, (25,20), a$ from alternative b to alternative a , that doesn't contain the link de . Therefore, if we had to recalculate the strengths of the strongest paths from alternative a to alternative b and from alternative b to alternative a based on the fact that the link de has been declared *forbidden* { what we don't have to do, because each of (5.2.3.1) – (5.2.3.3) is resolved separately, based on its own set of *non-forbidden* links }, we would get $P_\sigma[a,b] <_\sigma P_\sigma[b,a]$.

Furthermore, the link de is in the strongest path from alternative c to alternative b . And the strongest path $c, (30,15), d, (22,23), b$ from alternative c to alternative b , that doesn't contain the link de , is weaker than the strongest path $b, (26,19), c$ from alternative b to alternative c , that doesn't contain the link de . Therefore, if we had to recalculate the strengths of the strongest paths from alternative b to alternative c and from alternative c to alternative b based on the fact that the link de has been declared *forbidden*, we would get $P_\sigma[b,c] >_\sigma P_\sigma[c,b]$.

So example 12 (section 3.12) demonstrates that it can happen that (5.2.3.1) – (5.2.3.3) are resolved based on different sets of *non-forbidden* links. However, this is not a problem because — it doesn't matter whether $P_\sigma[c,a] \approx_\sigma P_\sigma[a,c]$ is resolved to $P_\sigma[c,a] >_\sigma P_\sigma[a,c]$ or to $P_\sigma[c,a] <_\sigma P_\sigma[a,c]$ — transitivity will never be violated.

5.2.4. Part 4

Suppose, before we start declaring links *forbidden*, we have:

$$(5.2.4.1) \quad P_\sigma[a,b] \approx_\sigma P_\sigma[b,a].$$

$$(5.2.4.2) \quad P_\sigma[b,c] \approx_\sigma P_\sigma[c,b].$$

$$(5.2.4.3) \quad P_\sigma[c,a] >_\sigma P_\sigma[a,c].$$

With (5.2.4.3), we get $ca \in \mathcal{O}$ and, therefore, $ca \in \mathcal{O}_{final}(\sigma)$.

As the tie (5.2.4.1) and the tie (5.2.4.2) are resolved separately, it seems to be possible that they are resolved based on different sets of *non-forbidden* links, so that the transitivity of $\mathcal{O}_{final}(\sigma)$ doesn't follow directly from the transitivity of $\mathcal{O}$. It seems to be possible that the tie (5.2.4.1) is resolved to $P_\sigma[a,b] >_\sigma P_\sigma[b,a]$ and that simultaneously — as other links are declared *forbidden* during the process of resolving the tie (5.2.4.2), so that the strengths of the strongest paths are determined based on different sets of *non-forbidden* links — the tie (5.2.4.2) is resolved to $P_\sigma[b,c] >_\sigma P_\sigma[c,b]$, so that the transitivity of $\mathcal{O}_{final}(\sigma)$ is violated. However, the following proof shows that transitivity will never be violated.

As fg is the weakest link in the strongest path from alternative b to alternative c , we get

$$(5.2.4.8) \quad P_{\sigma}[b,f] >_{\sigma} (N[f,g], N[g,f]).$$

$$(5.2.4.9) \quad P_{\sigma}[g,c] >_{\sigma} (N[f,g], N[g,f]).$$

As fg is the weakest link in the strongest path from alternative c to alternative b , we get

$$(5.2.4.10) \quad P_{\sigma}[c,f] >_{\sigma} (N[f,g], N[g,f]).$$

$$(5.2.4.11) \quad P_{\sigma}[g,b] >_{\sigma} (N[f,g], N[g,f]).$$

With (5.2.4.4), (5.2.4.5), (5.2.4.8), and (5.2.4.9), we get: $a \rightarrow d \rightarrow e \rightarrow b \rightarrow f \rightarrow g \rightarrow c$ is a path from alternative a to alternative c with a strength of $\min_{\sigma} \{ (N[d,e], N[e,d]), (N[f,g], N[g,f]) \}$. Therefore, with (5.2.4.3), we get

$$(5.2.4.12) \quad P_{\sigma}[c,a] >_{\sigma} \min_{\sigma} \{ (N[d,e], N[e,d]), (N[f,g], N[g,f]) \}.$$

Case 1: Suppose

$$(5.2.4.13a) \quad (N[d,e], N[e,d]) >_{\sigma} (N[f,g], N[g,f]).$$

Then, with (5.2.4.12), (5.2.4.4), (5.2.4.13a), and (5.2.4.5), we get: $c \rightarrow a \rightarrow d \rightarrow e \rightarrow b$ is a path from alternative c to alternative b with a strength of more than $(N[f,g], N[g,f])$. But this is a contradiction to the presumption that fg is the weakest link in the strongest path from alternative c to alternative b .

Case 2: Suppose

$$(5.2.4.13b) \quad (N[d,e], N[e,d]) <_{\sigma} (N[f,g], N[g,f]).$$

Then, with (5.2.4.8), (5.2.4.13b), (5.2.4.9), and (5.2.4.12), we get: $b \rightarrow f \rightarrow g \rightarrow c \rightarrow a$ is a path from alternative b to alternative a with a strength of more than $(N[d,e], N[e,d])$. But this is a contradiction to the presumption that de is the weakest link in the strongest path from alternative b to alternative a .

As (5.2.4.13a) and (5.2.4.13b) are not possible, we get

$$(5.2.4.13c) \quad (N[d,e], N[e,d]) \approx_{\sigma} (N[f,g], N[g,f]).$$

As there are no links of equivalent strengths, (5.2.4.13c) means that de and fg are the same link. So to resolve (5.2.4.1) and (5.2.4.2), the same link is declared *forbidden*.

Therefore, the strongest paths have the following structure:

Without loss of generality, we can also say that the same link is declared *forbidden* in the process of resolving (5.2.4.3). The reason: With (5.2.4.12), we get that the link de cannot be in the strongest path from alternative c to alternative a . Therefore, the strongest path from alternative c to alternative a cannot be weakened by declaring the link de *forbidden*. The strongest path from alternative a to alternative c can be weakened by declaring the link de *forbidden*. But as we already know from (5.2.4.3) that the strongest path from alternative c to alternative a is stronger than the strongest path from alternative a to alternative c , declaring the link de *forbidden* cannot have an impact on the resolution of (5.2.4.3).

When the link de is declared *forbidden*, we get one of the following cases:

Case A: We still get $P_σ[a,b] \approx_σ P_σ[b,a]$ and $P_σ[b,c] \approx_σ P_σ[c,b]$. In this case, with the same argumentation as in cases 1–2 we get that the same link, say de , is the weakest link in the strongest path from alternative a to alternative b , the weakest link in the strongest path from alternative b to alternative a , the weakest link in the strongest path from alternative b to alternative c , and the weakest link in the strongest path from alternative c to alternative b . So we can proceed with declaring the link de *forbidden* until we get one of the cases B–G.

Case B: We get ($P_σ[a,b] <_σ P_σ[b,a]$ and $P_σ[b,c] <_σ P_σ[c,b]$) or ($P_σ[a,b] <_σ P_σ[b,a]$ and $P_σ[b,c] >_σ P_σ[c,b]$) or ($P_σ[a,b] >_σ P_σ[b,a]$ and $P_σ[b,c] <_σ P_σ[c,b]$). In this case, we succeeded in resolving (5.2.4.1) – (5.2.4.3) without violating transitivity.

Case C: We get $P_σ[a,b] >_σ P_σ[b,a]$ and $P_σ[b,c] \approx_σ P_σ[c,b]$. This case is not possible because, after the link de has been declared *forbidden*, (5.2.4.1) – (5.2.4.3) are still calculated based on the same set of *non-forbidden* links. So with $P_σ[c,a] >_σ P_σ[a,c]$ and $P_σ[a,b] >_σ P_σ[b,a]$ and the transitivity, as proven

in section 4.1 for cases where all paths are based on the same set of *non-forbidden* links, we would immediately get $P_\sigma[b,c] <_\sigma P_\sigma[c,b]$.

Case D: We get $P_\sigma[a,b] \approx_\sigma P_\sigma[b,a]$ and $P_\sigma[b,c] >_\sigma P_\sigma[c,b]$. This case is not possible because, after the link *de* has been declared *forbidden*, (5.2.4.1) – (5.2.4.3) are still calculated based on the same set of *non-forbidden* links. So with $P_\sigma[c,a] >_\sigma P_\sigma[a,c]$ and $P_\sigma[b,c] >_\sigma P_\sigma[c,b]$ and the transitivity, as proven in section 4.1 for cases where all paths are based on the same set of *non-forbidden* links, we would immediately get $P_\sigma[a,b] <_\sigma P_\sigma[b,a]$.

Case E: We get $P_\sigma[a,b] >_\sigma P_\sigma[b,a]$ and $P_\sigma[b,c] >_\sigma P_\sigma[c,b]$. This case is not possible because, after the link *de* has been declared *forbidden*, (5.2.4.1) – (5.2.4.3) are still calculated based on the same set of *non-forbidden* links. So $P_\sigma[a,b] >_\sigma P_\sigma[b,a]$, $P_\sigma[b,c] >_\sigma P_\sigma[c,b]$, and $P_\sigma[c,a] >_\sigma P_\sigma[a,c]$ together violate transitivity, as proven in section 4.1 for cases where all paths are based on the same set of *non-forbidden* links.

Case F: We get $P_\sigma[a,b] \approx_\sigma P_\sigma[b,a]$ and $P_\sigma[b,c] <_\sigma P_\sigma[c,b]$. This case is identical to the situation in section 5.2.2. It is possible that $P_\sigma[a,b] \approx_\sigma P_\sigma[b,a]$ is resolved based on a different set of *non-forbidden* links. However, this is not a problem because — it doesn’t matter whether $P_\sigma[a,b] \approx_\sigma P_\sigma[b,a]$ is resolved to $P_\sigma[a,b] >_\sigma P_\sigma[b,a]$ or to $P_\sigma[a,b] <_\sigma P_\sigma[b,a]$ — transitivity will never be violated.

Case G: We get $P_\sigma[a,b] <_\sigma P_\sigma[b,a]$ and $P_\sigma[b,c] \approx_\sigma P_\sigma[c,b]$. This case is identical to the situation in section 5.2.3. It is possible that $P_\sigma[b,c] \approx_\sigma P_\sigma[c,b]$ is resolved based on a different set of *non-forbidden* links. However, this is not a problem because — it doesn’t matter whether $P_\sigma[b,c] \approx_\sigma P_\sigma[c,b]$ is resolved to $P_\sigma[b,c] >_\sigma P_\sigma[c,b]$ or to $P_\sigma[b,c] <_\sigma P_\sigma[c,b]$ — transitivity will never be violated.

The following table shows that cases A–G cover all possible combinations. Therefore, it has been proven for every possible situation that, when we resolve (5.2.4.1) – (5.2.4.3) as prescribed in section 5.1, then transitivity will never be violated.

$P_\sigma[a,b] \approx_\sigma P_\sigma[b,a]$ and $P_\sigma[b,c] \approx_\sigma P_\sigma[c,b]$	→ case A
$P_\sigma[a,b] \approx_\sigma P_\sigma[b,a]$ and $P_\sigma[b,c] >_\sigma P_\sigma[c,b]$	→ case D
$P_\sigma[a,b] \approx_\sigma P_\sigma[b,a]$ and $P_\sigma[b,c] <_\sigma P_\sigma[c,b]$	→ case F
$P_\sigma[a,b] >_\sigma P_\sigma[b,a]$ and $P_\sigma[b,c] \approx_\sigma P_\sigma[c,b]$	→ case C
$P_\sigma[a,b] >_\sigma P_\sigma[b,a]$ and $P_\sigma[b,c] >_\sigma P_\sigma[c,b]$	→ case E
$P_\sigma[a,b] >_\sigma P_\sigma[b,a]$ and $P_\sigma[b,c] <_\sigma P_\sigma[c,b]$	→ case B
$P_\sigma[a,b] <_\sigma P_\sigma[b,a]$ and $P_\sigma[b,c] \approx_\sigma P_\sigma[c,b]$	→ case G
$P_\sigma[a,b] <_\sigma P_\sigma[b,a]$ and $P_\sigma[b,c] >_\sigma P_\sigma[c,b]$	→ case B
$P_\sigma[a,b] <_\sigma P_\sigma[b,a]$ and $P_\sigma[b,c] <_\sigma P_\sigma[c,b]$	→ case B

□

As de is the weakest link in the strongest path from alternative a to alternative b , we get

$$(5.2.5.4) \quad P_{\sigma}[a,d] >_{\sigma} (N[d,e], N[e,d]).$$

$$(5.2.5.5) \quad P_{\sigma}[e,b] >_{\sigma} (N[d,e], N[e,d]).$$

As de is the weakest link in the strongest path from alternative b to alternative a , we get

$$(5.2.5.6) \quad P_{\sigma}[b,d] >_{\sigma} (N[d,e], N[e,d]).$$

$$(5.2.5.7) \quad P_{\sigma}[e,a] >_{\sigma} (N[d,e], N[e,d]).$$

As fg is the weakest link in the strongest path from alternative b to alternative c , we get

$$(5.2.5.8) \quad P_{\sigma}[b,f] >_{\sigma} (N[f,g], N[g,f]).$$

$$(5.2.5.9) \quad P_{\sigma}[g,c] >_{\sigma} (N[f,g], N[g,f]).$$

As fg is the weakest link in the strongest path from alternative c to alternative b , we get

$$(5.2.5.10) \quad P_{\sigma}[c,f] >_{\sigma} (N[f,g], N[g,f]).$$

$$(5.2.5.11) \quad P_{\sigma}[g,b] >_{\sigma} (N[f,g], N[g,f]).$$

As hi is the weakest link in the strongest path from alternative c to alternative a , we get

$$(5.2.5.12) \quad P_{\sigma}[c,h] >_{\sigma} (N[h,i], N[i,h]).$$

$$(5.2.5.13) \quad P_{\sigma}[i,a] >_{\sigma} (N[h,i], N[i,h]).$$

As hi is the weakest link in the strongest path from alternative a to alternative c , we get

$$(5.2.5.14) \quad P_{\sigma}[a,h] >_{\sigma} (N[h,i], N[i,h]).$$

$$(5.2.5.15) \quad P_{\sigma}[i,c] >_{\sigma} (N[h,i], N[i,h]).$$

Case 1: Suppose

$$(5.2.5.16a) \quad (N[d,e], N[e,d]) <_{\sigma} (N[f,g], N[g,f]).$$

$$(5.2.5.17a) \quad (N[d,e], N[e,d]) <_{\sigma} (N[h,i], N[i,h]).$$

Then, with (5.2.5.14), (5.2.5.17a), (5.2.5.15), (5.2.5.10), (5.2.5.16a), and (5.2.5.11), we get: $a \rightarrow h \rightarrow i \rightarrow c \rightarrow f \rightarrow g \rightarrow b$ is a path from alternative a to alternative b with a strength of more than $(N[d,e], N[e,d])$. But this is a contradiction to the presumption that de is the weakest link in the strongest path from alternative a to alternative b .

Similarly, with (5.2.5.8), (5.2.5.16a), (5.2.5.9), (5.2.5.12), (5.2.5.17a), and (5.2.5.13), we get: $b \rightarrow f \rightarrow g \rightarrow c \rightarrow h \rightarrow i \rightarrow a$ is a path from alternative b to alternative a with a strength of more than $(N[d,e], N[e,d])$. But this is a contradiction to the presumption that de is the weakest link in the strongest path from alternative b to alternative a .

Case 2: Suppose

$$(5.2.5.16b) \quad (N[f,g], N[g,f]) <_{\sigma} (N[d,e], N[e,d]).$$

$$(5.2.5.17b) \quad (N[f,g], N[g,f]) <_{\sigma} (N[h,i], N[i,h]).$$

Then, with (5.2.5.6), (5.2.5.16b), (5.2.5.7), (5.2.5.14), (5.2.5.17b), and (5.2.5.15), we get: $b \rightarrow d \rightarrow e \rightarrow a \rightarrow h \rightarrow i \rightarrow c$ is a path from alternative b to alternative c with a strength of more than $(N[f,g], N[g,f])$. But this is a contradiction to the presumption that fg is the weakest link in the strongest path from alternative b to alternative c .

Similarly, with (5.2.5.12), (5.2.5.17b), (5.2.5.13), (5.2.5.4), (5.2.5.16b), and (5.2.5.5), we get: $c \rightarrow h \rightarrow i \rightarrow a \rightarrow d \rightarrow e \rightarrow b$ is a path from alternative c to alternative b with a strength of more than $(N[f,g], N[g,f])$. But this is a contradiction to the presumption that fg is the weakest link in the strongest path from alternative c to alternative b .

Case 3: Suppose

$$(5.2.5.16c) \quad (N[h,i], N[i,h]) <_{\sigma} (N[d,e], N[e,d]).$$

$$(5.2.5.17c) \quad (N[h,i], N[i,h]) <_{\sigma} (N[f,g], N[g,f]).$$

Then, with (5.2.5.10), (5.2.5.17c), (5.2.5.11), (5.2.5.6), (5.2.5.16c), and (5.2.5.7), we get: $c \rightarrow f \rightarrow g \rightarrow b \rightarrow d \rightarrow e \rightarrow a$ is a path from alternative c to alternative a with a strength of more than $(N[h,i], N[i,h])$. But this is a contradiction to the presumption that hi is the weakest link in the strongest path from alternative c to alternative a .

Similarly, with (5.2.5.4), (5.2.5.16c), (5.2.5.5), (5.2.5.8), (5.2.5.17c), and (5.2.5.9), we get: $a \rightarrow d \rightarrow e \rightarrow b \rightarrow f \rightarrow g \rightarrow c$ is a path from alternative a to alternative c with a strength of more than $(N[h,i], N[i,h])$. But this is a contradiction to the presumption that hi is the weakest link in the strongest path from alternative a to alternative c .

With cases 1–3, we get that none of the links de , fg , hi can be weaker than each of the other two links. Without loss of generality, we can presume that the link hi is the strongest one of the links de , fg , hi . So we get

$$(5.2.5.18) \quad (N[d,e], N[e,d]) \approx_{\sigma} (N[f,g], N[g,f]) \lesssim_{\sigma} (N[h,i], N[i,h]).$$

We can ignore the case $(N[d,e], N[e,d]) \approx_{\sigma} (N[f,g], N[g,f]) \approx_{\sigma} (N[h,i], N[i,h])$ because in this case the links de , fg , hi are the same link so that for each of (5.2.5.1) – (5.2.5.3) the same link is declared *forbidden* first so that, afterwards, each of (5.2.5.1) – (5.2.5.3) is still resolved based on the same set of *non-forbidden* links.

So without loss of generality, we get

$$(5.2.5.19) \quad (N[d,e], N[e,d]) \approx_{\sigma} (N[f,g], N[g,f]) <_{\sigma} (N[h,i], N[i,h]).$$

As there are no links of equivalent strengths, (5.2.5.19) means that the link de and the link fg must be the same link. Therefore, the strongest paths have the following structure:

Without loss of generality, we can also say that, when we resolve (5.2.5.1) – (5.2.5.3), then, at each stage, the weakest of the weakest links of the current strongest paths is declared *forbidden*. So in our situation, the link de is declared *forbidden* next.

Since $(N[d,e], N[e,d]) <_{\sigma} (N[h,i], N[i,h]) \approx_{\sigma} P_{\sigma}[c,a] \approx_{\sigma} P_{\sigma}[a,c]$, the link de cannot be in the strongest path from alternative c to alternative a or in the strongest path from alternative a to alternative c . Therefore, declaring the link de *forbidden* cannot have an impact on the strongest path from alternative c to alternative a or on the strongest path from alternative a to alternative c .

When the link de is declared *forbidden*, we get one of the following cases:

Case A: We still get $P_{\sigma}[a,b] \approx_{\sigma} P_{\sigma}[b,a]$ and $P_{\sigma}[b,c] \approx_{\sigma} P_{\sigma}[c,b]$. In this case, with the same argumentation as in cases 1–2 we get that the same link, say de , is the weakest link in the strongest path from alternative a to alternative b , the weakest link in the strongest path from alternative b to alternative a , the weakest link in the strongest path from alternative b to alternative c , and the weakest link in the strongest path from alternative c to alternative b . So we can proceed with declaring the link de *forbidden* until we get one of the cases B–F.

Case B: We get $P_{\sigma}[a,b] >_{\sigma} P_{\sigma}[b,a]$ and $P_{\sigma}[b,c] >_{\sigma} P_{\sigma}[c,b]$. This case is not possible because, after the link de has been declared *forbidden*, (5.2.5.1) – (5.2.5.3) are still calculated based on the same set of *non-forbidden* links. With $P_{\sigma}[a,b] >_{\sigma} P_{\sigma}[b,a]$ and $P_{\sigma}[b,c] >_{\sigma} P_{\sigma}[c,b]$ and the transitivity, as proven in section 4.1 for cases where all paths are based on the same set of *non-forbidden* links, we would immediately get $P_{\sigma}[c,a] <_{\sigma} P_{\sigma}[a,c]$. But this is a contradiction to the fact that the link de cannot have been in the strongest path from alternative c to alternative a or in the strongest path from alternative a to alternative c , so that declaring the link de *forbidden* cannot have an impact on $P_{\sigma}[c,a] \approx_{\sigma} P_{\sigma}[a,c]$.

Case C: We get $P_{\sigma}[a,b] <_{\sigma} P_{\sigma}[b,a]$ and $P_{\sigma}[b,c] <_{\sigma} P_{\sigma}[c,b]$. This case is not possible because, after the link de has been declared *forbidden*, (5.2.5.1) – (5.2.5.3) are still calculated based on the same set of *non-forbidden* links. With $P_{\sigma}[a,b] <_{\sigma} P_{\sigma}[b,a]$ and $P_{\sigma}[b,c] <_{\sigma} P_{\sigma}[c,b]$ and the transitivity, as proven in section 4.1 for cases where all paths are based on the same set of *non-forbidden* links, we would immediately get $P_{\sigma}[c,a] >_{\sigma} P_{\sigma}[a,c]$. But this is a contradiction to the fact that the link de cannot have been in the strongest path from alternative c to alternative a or in the strongest path from alternative a to alternative c , so that declaring the link de *forbidden* cannot have an impact on $P_{\sigma}[c,a] \approx_{\sigma} P_{\sigma}[a,c]$.

Case D: We get ($P_\sigma[a,b] >_\sigma P_\sigma[b,a]$ and $P_\sigma[b,c] \approx_\sigma P_\sigma[c,b]$) or ($P_\sigma[a,b] <_\sigma P_\sigma[b,a]$ and $P_\sigma[b,c] \approx_\sigma P_\sigma[c,b]$) or ($P_\sigma[a,b] \approx_\sigma P_\sigma[b,a]$ and $P_\sigma[b,c] >_\sigma P_\sigma[c,b]$) or ($P_\sigma[a,b] \approx_\sigma P_\sigma[b,a]$ and $P_\sigma[b,c] <_\sigma P_\sigma[c,b]$). This case is not possible because we have seen in (5.2.4.13a) – (5.2.4.13c) that, when we have a situation with $P_\sigma[x,y] \approx_\sigma P_\sigma[y,x]$, $P_\sigma[y,z] \approx_\sigma P_\sigma[z,y]$, and $P_\sigma[z,x] >_\sigma P_\sigma[x,z]$, then the weakest link in the strongest path from alternative x to alternative y , the weakest link in the strongest path from alternative y to alternative x , the weakest link in the strongest path from alternative y to alternative z , and the weakest link in the strongest path from alternative z to alternative y must be the same link. But this is not possible because (5.2.5.19) says that the link hi is stronger than the link de .

Case E: We get $P_\sigma[a,b] <_\sigma P_\sigma[b,a]$ and $P_\sigma[b,c] >_\sigma P_\sigma[c,b]$. This case is identical to the situation in section 5.2.2. It is possible that $P_\sigma[c,a] \approx_\sigma P_\sigma[a,c]$ is resolved based on a different set of *non-forbidden* links. However, this is not a problem because — it doesn’t matter whether $P_\sigma[a,c] \approx_\sigma P_\sigma[c,a]$ is resolved to $P_\sigma[a,c] >_\sigma P_\sigma[c,a]$ or to $P_\sigma[a,c] <_\sigma P_\sigma[c,a]$ — transitivity will never be violated.

Case F: We get $P_\sigma[a,b] >_\sigma P_\sigma[b,a]$ and $P_\sigma[b,c] <_\sigma P_\sigma[c,b]$. This case is identical to the situation in section 5.2.3. It is possible that $P_\sigma[c,a] \approx_\sigma P_\sigma[a,c]$ is resolved based on a different set of *non-forbidden* links. However, this is not a problem because — it doesn’t matter whether $P_\sigma[a,c] \approx_\sigma P_\sigma[c,a]$ is resolved to $P_\sigma[a,c] >_\sigma P_\sigma[c,a]$ or to $P_\sigma[a,c] <_\sigma P_\sigma[c,a]$ — transitivity will never be violated.

The following table shows that cases A–F cover all possible combinations. Therefore, it has been proven for every possible situation that, when we resolve (5.2.5.1) – (5.2.5.3) as prescribed in section 5.1, then transitivity will never be violated.

$P_\sigma[a,b] \approx_\sigma P_\sigma[b,a]$ and $P_\sigma[b,c] \approx_\sigma P_\sigma[c,b]$	→ case A
$P_\sigma[a,b] \approx_\sigma P_\sigma[b,a]$ and $P_\sigma[b,c] >_\sigma P_\sigma[c,b]$	→ case D
$P_\sigma[a,b] \approx_\sigma P_\sigma[b,a]$ and $P_\sigma[b,c] <_\sigma P_\sigma[c,b]$	→ case D
$P_\sigma[a,b] >_\sigma P_\sigma[b,a]$ and $P_\sigma[b,c] \approx_\sigma P_\sigma[c,b]$	→ case D

□

5.3. Analysis

5.3.1. The Probabilistic Framework

An election method is simply a mapping from some input to some output. In section 2.1, we presumed that the output is (1) a strict partial order O on A and (2) a set $\emptyset \neq S \subseteq A$ of potential winners. In the probabilistic framework, the output of an election method is a probability distribution $p[O] \in \mathbb{R}$ on $\mathcal{LO}_A$, where $\mathcal{LO}_A$ is the set of linear orders on A .

We get

$$(5.3.1.1) \quad \forall O \in \mathcal{LO}_A: p[O] \geq 0.$$

$$(5.3.1.2) \quad \sum (p[O] \mid O \in \mathcal{LO}_A) = 1.$$

Suppose $q[a,b] \in \mathbb{R}$ is the probability for $ab \in O$ (i.e. the probability that alternative $a \in A$ is ranked ahead of alternative $b \in A \setminus \{a\}$ in the collective ranking O).

Then, we get

$$(5.3.1.3) \quad q[a,b] := \sum (p[O] \mid O \in \mathcal{LO}_A \text{ with } ab \in O).$$

$$(5.3.1.4) \quad \forall a,b \in A: q[a,b] \geq 0.$$

$$(5.3.1.5) \quad \forall a,b \in A: q[a,b] + q[b,a] = 1.$$

Suppose $r[a] \in \mathbb{R}$ is the probability that alternative $a \in A$ is elected.

Then, we get

$$(5.3.1.6) \quad r[a] := \sum (p[O] \mid O \in \mathcal{LO}_A \text{ with } ab \in O \text{ for all } b \in A \setminus \{a\}).$$

$$(5.3.1.7) \quad \forall a \in A: r[a] \geq 0.$$

$$(5.3.1.8) \quad \sum (r[a] \mid a \in A) = 1.$$

5.3.2. Decisiveness

Definition:

An election method satisfies *decisiveness* if (for every given number of alternatives) the proportion of profiles without a linear order $O \in \mathcal{LO}_A$ with $p[O] = 1$ tends to zero as the number of voters in the profile tends to infinity.

Claim:

If $>_D$ satisfies (2.1.1), then the Schulze method $O_{final} := \cap O_{final}(\sigma)$, as defined in section 5.1, satisfies decisiveness.

Proof (overview):

1. Suppose the number of alternatives is fixed. We prove that, when the number of voters in the profile tends to infinity, the probability, that there are links with equivalent strengths, goes to zero. We then get: The probability, that there are links ef and gh with $ef \approx_\sigma gh$, goes to zero.
2. We prove that (1) the link ij cannot be in the strongest path from alternative j to alternative i and (2) the link ji cannot be in the strongest path from alternative i to alternative j . Therefore, when we resolve the tie $P_\sigma[i,j] \approx_\sigma P_\sigma[j,i]$, it can neither happen that the link ij is declared *forbidden* nor that the link ji is declared *forbidden*. Therefore, in worst case, when there are no other paths of *non-forbidden* links anymore, $P_\sigma[i,j] \approx_\sigma P_\sigma[j,i]$ is resolved to $ij \in O$ when $ij >_\sigma ji$ and to $ji \in O$ when $ij <_\sigma ji$. So the algorithm in section 5.1 step 4 always terminates before all links have been declared *forbidden*.

Remark:

When there is a unique linear order (i.e. a linear order $O \in \mathcal{LO}_A$ with $p[O] = 1$) then, with (5.3.1.6), we get that there is also a unique winner (i.e. an alternative $a \in A$ with $r[a] = 1$):

$$(\exists O \in \mathcal{LO}_A: p[O] = 1) \Rightarrow (\exists a \in A: r[a] = 1).$$

5.3.3. Pareto

In the probabilistic framework, the *Pareto criterion* says that, when no voter strictly prefers alternative $b \in A$ to alternative $a \in A$ [see (5.3.3.1)] and at least one voter strictly prefers alternative a to alternative b [see (5.3.3.2)], then $r[b] = 0$.

Definition:

An election method satisfies the *Pareto criterion* if the following holds:

Suppose:

$$(5.3.3.1) \quad \forall v \in V: a \succeq_v b.$$

$$(5.3.3.2) \quad \exists v \in V: a \succ_v b.$$

Then:

$$(5.3.3.3) \quad q[a, b] = 1.$$

$$(5.3.3.4) \quad \forall f \in A \setminus \{a, b\}: q[a, f] \geq q[b, f].$$

$$(5.3.3.5) \quad \forall f \in A \setminus \{a, b\}: q[f, a] \leq q[f, b].$$

$$(5.3.3.6) \quad r[b] = 0.$$

Claim:

If $\succ_D$ satisfies (2.1.1), then the Schulze method $O_{final}(\sigma)$, as defined in section 5.1, satisfies the Pareto criterion.

Proof (overview):

With (5.1.1) and (5.3.3.1), we prove

$$(5.3.3.7) \quad \forall e \in A \setminus \{a, b\}: ae \succeq_\sigma be \text{ with certainty.}$$

With (5.1.1) and (5.3.3.1), we prove

$$(5.3.3.8) \quad \forall e \in A \setminus \{a, b\}: eb \succeq_\sigma ea \text{ with certainty.}$$

With (5.1.1), (5.3.3.1), and (5.3.3.2), we prove

$$(5.3.3.9) \quad ab \succ_\sigma ba \text{ with certainty.}$$

With (5.3.3.7), (5.3.3.8), and (5.3.3.9), we prove

$$(5.3.3.10) \quad ab \in O_{final}(\sigma) \text{ with certainty.}$$

The rest of the proof is identical to the proof in section 4.4.2.

5.3.4. Reversal Symmetry

In the probabilistic framework, *reversal symmetry* says that, when $\succ_v$ is reversed for all $v \in V$, then $r^{\text{old}}[a] + r^{\text{new}}[a] \leq 1$ for all $a \in A$. Otherwise, if $r^{\text{old}}[a] + r^{\text{new}}[a]$ was larger than 1 for some alternative $a \in A$, then this would mean that, with a probability of at least $r^{\text{old}}[a] + r^{\text{new}}[a] - 1 > 0$, alternative a is identified as best alternative and, simultaneously, identified as worst alternative.

Suppose $O^{\text{reverse}} \in \mathcal{LO}_A$ is the reversal of $O \in \mathcal{LO}_A$.

That means:

$$(5.3.4.1) \quad \forall a, b \in A: ab \in O \Leftrightarrow ba \in O^{\text{reverse}}.$$

Definition:

An election method satisfies *reversal symmetry* if the following holds:

Suppose:

$$(5.3.4.2) \quad \forall e, f \in A \forall v \in V: e \succ_v^{\text{old}} f \Leftrightarrow f \succ_v^{\text{new}} e.$$

Then:

$$(5.3.4.3) \quad \forall O \in \mathcal{LO}_A: p^{\text{old}}[O] = p^{\text{new}}[O^{\text{reverse}}].$$

$$(5.3.4.4) \quad \forall a, b \in A: q^{\text{old}}[a, b] = q^{\text{new}}[b, a].$$

$$(5.3.4.5) \quad \forall a \in A: r^{\text{old}}[a] + r^{\text{new}}[a] \leq 1.$$

Claim:

Suppose $\succ_D$ satisfies (2.1.2). Then the Schulze method $O_{\text{final}}(\sigma)$, as defined in sections 5.1, satisfies reversal symmetry.

Proof (overview):

(2.1.2) guarantees that, when $\succ_v$ is reversed for all $v \in V$, then also the TBRL $\succ_\sigma$, as defined in section 5.1, is reversed. So the probability that O is chosen in the original situation is identical to the probability that O^{reverse} is chosen in the reversed situation. As we have presumed in section 2.1 that there are at least 2 alternatives in A , $a \in A$ cannot be the maximum element of O and simultaneously the maximum element of O^{reverse} . Therefore, we get (5.3.4.5).

Example 13:

(α) When we apply the proposed method to example 13 (section 3.13), we first calculate the TBRL $>_{\sigma}$.

We have:

$$\begin{aligned} (N[b,c], N[c,b]) &\approx_D (4,1). \\ (N[a,b], N[b,a]) &\approx_D (3,2). \\ (N[c,a], N[a,c]) &\approx_D (3,2). \\ (N[a,c], N[c,a]) &\approx_D (2,3). \\ (N[b,a], N[a,b]) &\approx_D (2,3). \\ (N[c,b], N[b,c]) &\approx_D (1,4). \end{aligned}$$

So we start with $bc >_{\sigma} ab \approx_{\sigma} ca >_{\sigma} ac \approx_{\sigma} ba >_{\sigma} cb$.

Case I: With a probability of 2/5, one of the $a >_v b >_v c$ voters is chosen first. $ab \approx_{\sigma} ca$ is then completed to $ab >_{\sigma} ca$ because this voter supports the link ab and opposes the link ca . $ac \approx_{\sigma} ba$ is completed to $ac >_{\sigma} ba$ because this voter supports the link ac and opposes the link ba . So the TBRL $>_{\sigma}$ is completed to $bc >_{\sigma} ab >_{\sigma} ca >_{\sigma} ac >_{\sigma} ba >_{\sigma} cb$.

Case II: With a probability of 2/5, one of the $b >_v c >_v a$ voters is chosen first. $ab \approx_{\sigma} ca$ is then completed to $ca >_{\sigma} ab$ because this voter supports the link ca and opposes the link ab . $ac \approx_{\sigma} ba$ is completed to $ba >_{\sigma} ac$ because this voter supports the link ba and opposes the link ac . So the TBRL $>_{\sigma}$ is completed to $bc >_{\sigma} ca >_{\sigma} ab >_{\sigma} ba >_{\sigma} ac >_{\sigma} cb$.

Case III: With a probability of 1/5, the $c >_v a >_v b$ voter is chosen first. As this voter supports both links ab and ca , this voter cannot be used to complete $ab \approx_{\sigma} ca$. As this voter opposes both links ac and ba , this voter cannot be used to complete $ac \approx_{\sigma} ba$. With a probability of 1/2, one of the $a >_v b >_v c$ voters is chosen second; the TBRL $>_{\sigma}$ is then completed to $bc >_{\sigma} ab >_{\sigma} ca >_{\sigma} ac >_{\sigma} ba >_{\sigma} cb$ as described in Case I. With a probability of 1/2, one of the $b >_v c >_v a$ voters is chosen second; the TBRL $>_{\sigma}$ is then completed to $bc >_{\sigma} ca >_{\sigma} ab >_{\sigma} ba >_{\sigma} ac >_{\sigma} cb$ as described in Case II.

So with a probability of 1/2, the TBRL $>_{\sigma}$ is completed to $bc >_{\sigma} ab >_{\sigma} ca >_{\sigma} ac >_{\sigma} ba >_{\sigma} cb$ and, with a probability of 1/2, the TBRL $>_{\sigma}$ is completed to $bc >_{\sigma} ca >_{\sigma} ab >_{\sigma} ba >_{\sigma} ac >_{\sigma} cb$.

(β) Suppose the TBRL $bc >_{\sigma} ab >_{\sigma} ca >_{\sigma} ac >_{\sigma} ba >_{\sigma} cb$ is used. The weakest link in the strongest path from alternative a to alternative b is ab . The weakest link in the strongest path from alternative b to alternative a is ca . As $ab >_{\sigma} ca$, we get $P_D[a,b] >_D P_D[b,a]$. Alternative a is the final winner.

Suppose the TBRL $bc >_{\sigma} ca >_{\sigma} ab >_{\sigma} ba >_{\sigma} ac >_{\sigma} cb$ is used. The weakest link in the strongest path from alternative a to alternative b is ab . The weakest link in the strongest path from alternative b to alternative a is ca . As $ca >_{\sigma} ab$, we get $P_D[b,a] >_D P_D[a,b]$. Alternative b is the final winner.

So in example 13, we get: $r^{\text{old}}[a] = 0.5$ and $r^{\text{old}}[b] = 0.5$.

(γ) When the individual ballots are reversed, we get:

Example 13 (new):

2	voters	$c \succ_v b \succ_v a$
2	voters	$a \succ_v c \succ_v b$
1	voter	$b \succ_v a \succ_v c$

When we rename the alternatives b and c and reorder the voters, we see that example 13 (new) is identical to example 13. So with anonymity and neutrality, we get $r^{\text{new}}[a] = r^{\text{old}}[a]$, $r^{\text{new}}[b] = r^{\text{old}}[c]$, and $r^{\text{new}}[c] = r^{\text{old}}[b]$. So we get: $r^{\text{new}}[a] = 0.5$ and $r^{\text{new}}[c] = 0.5$.

(δ) The interesting conclusion is that anonymity, neutrality, and reversal symmetry together imply $r^{\text{old}}[a] \leq 0.5$ in example 13, because anonymity and neutrality together imply $r^{\text{new}}[a] = r^{\text{old}}[a]$ and reversal symmetry implies $r^{\text{old}}[a] + r^{\text{new}}[a] \leq 1$.

5.3.5. Monotonicity

In the probabilistic framework, *monotonicity* says that, when some voters rank alternative $a \in A$ higher [see (4.6.1.1) and (4.6.1.2)] without changing the order in which they rank the other alternatives relatively to each other [see (4.6.1.3)], then $r[a]$ must not decrease.

Definition:

An election method satisfies *monotonicity* if the following holds:

Suppose $a \in A$. Suppose the ballots are modified as described in (4.6.1.1) – (4.6.1.3). Then

$$\begin{aligned}
 (5.3.5.1) \quad & \forall \emptyset \neq B \subseteq A \setminus \{a\}: \\
 & \sum (p^{\text{old}}[O] \mid O \in \mathcal{LO}_A \text{ with } ab \in O \text{ for all } b \in B) \\
 & \leq \sum (p^{\text{new}}[O] \mid O \in \mathcal{LO}_A \text{ with } ab \in O \text{ for all } b \in B). \\
 (5.3.5.2) \quad & \forall b \in A \setminus \{a\}: q^{\text{old}}[a, b] \leq q^{\text{new}}[a, b]. \\
 (5.3.5.3) \quad & r^{\text{old}}[a] \leq r^{\text{new}}[a].
 \end{aligned}$$

Claim:

If $\succ_D$ satisfies (2.1.1), then the Schulze method $O_{\text{final}}(\sigma)$, as defined in sections 5.1, satisfies monotonicity.

Proof (overview):

We prove that, when the ballots are modified as described in (4.6.1.1) – (4.6.1.3), then we get

$$\begin{aligned}
 (5.3.5.4) \quad & \forall c, d, e \in A \setminus \{a\}: \quad ac >_{\sigma}^{\text{old}} de \Rightarrow ac >_{\sigma}^{\text{new}} de. \\
 (5.3.5.5) \quad & \forall c, d, e \in A \setminus \{a\}: \quad ac \approx_{\sigma}^{\text{old}} de \Rightarrow ac \approx_{\sigma}^{\text{new}} de. \\
 (5.3.5.6) \quad & \forall c, d, e \in A \setminus \{a\}: \quad ca <_{\sigma}^{\text{old}} de \Rightarrow ca <_{\sigma}^{\text{new}} de. \\
 (5.3.5.7) \quad & \forall c, d, e \in A \setminus \{a\}: \quad ca \approx_{\sigma}^{\text{old}} de \Rightarrow ca \approx_{\sigma}^{\text{new}} de. \\
 (5.3.5.8) \quad & \forall c, d \in A \setminus \{a\}: \quad ac >_{\sigma}^{\text{old}} da \Rightarrow ac >_{\sigma}^{\text{new}} da. \\
 (5.3.5.9) \quad & \forall c, d \in A \setminus \{a\}: \quad ac \approx_{\sigma}^{\text{old}} da \Rightarrow ac \approx_{\sigma}^{\text{new}} da. \\
 (5.3.5.10) \quad & \forall c \in A \setminus \{a\}: \quad ac >_{\sigma}^{\text{old}} ca \Rightarrow ac >_{\sigma}^{\text{new}} ca. \\
 (5.3.5.11) \quad & \forall c \in A \setminus \{a\}: \quad ac \approx_{\sigma}^{\text{old}} ca \Rightarrow ac \approx_{\sigma}^{\text{new}} ca. \\
 (5.3.5.12) \quad & \forall b, c, d, e \in A \setminus \{a\}: \quad bc >_{\sigma}^{\text{old}} de \Leftrightarrow bc >_{\sigma}^{\text{new}} de.
 \end{aligned}$$

The rest of the proof is identical to the proof in section 4.6.1.

5.3.6. Independence of Clones

Independence of clones says that running a large number of similar alternatives, so-called *clones*, must not have any impact on the result of the elections (section 4.7).

When we define independence of clones for the probabilistic framework, we have to explicitly address the case where there are alternatives $a \in A$ such that every voter is indifferent between alternative a and alternative d . According to neutrality, both alternatives must then be elected with the same probability ($r^{\text{old}}[a] = r^{\text{old}}[d]$). When alternative d is replaced by a set of clones K (with $\| K \| > 1$), as defined in (4.7.1) – (4.7.3), and, again, every voter is indifferent between alternative a and every alternative $g \in K$ then, again, every alternative in $K \cup \{a\}$ must be elected with the same probability ($\forall g \in K: r^{\text{new}}[a] = r^{\text{new}}[g]$) so that the probability, that alternative a is chosen, necessarily drops (i.e.: $r^{\text{old}}[a] > r^{\text{new}}[a]$).

In an earlier version of this paper (Schulze, 2003), I addressed this case by explicitly presuming (1) $r^{\text{old}}[a] = 0$ or (2) that, for every alternative $a \in A \setminus \{d\}$, there is at least one voter $v \in V$ with $a \not\sim_v d$.

In this version, I address this case by explicitly specifying how $r^{\text{old}}[a]$ changes. Suppose $B \subseteq A^{\text{old}} \setminus \{d\}$ is the set of alternatives such that every voter is indifferent between alternative d and every alternative $a \in B$. See (5.3.6.1). Then, when alternative d is replaced by a set of clones K , $r[a]$ changes by the factor $(1 + \| B \|) / (\| K \| + \| B \|)$. See (5.3.6.6)(ii) and (5.3.6.7)(ii).

The conditions (4.7.4) – (4.7.13) and (5.3.6.2) – (5.3.6.10) are not independent conditions. Rather, I have arranged them according to the addressed aspects. For example, it is easy to see that (4.7.10) implies (4.7.7) or that (5.3.6.2) implies (5.3.6.3).

The conditions (4.7.4) – (4.7.13) and (5.3.6.2) – (5.3.6.10) are not very intuitive. The best way to understand them is by asking: “What would *random dictatorship* (with *random alternative* as a tie-breaker for those situations where there is a set of alternatives such that every voter is indifferent between every alternative of this set) do?”

Random dictatorship means that we randomly choose a voter $v \in V$ and the collective ranking is this voter’s individual ranking. When this voter is indifferent between some alternatives, then we randomly choose another voter and use his ranking to complete the collective ranking. We continue to randomly choose voters until either (1) the collective ranking is a complete order or (2) all voters have been used to complete the collective ranking.

Random alternative means that the alternatives are ranked randomly, regardless of how the voters vote.

Definition:

An election method is *independent of clones* if the following holds:

Suppose $d \in A^{\text{old}}$. Suppose $A^{\text{new}} := (A^{\text{old}} \cup K) \setminus \{d\}$.

Suppose $B \subseteq A^{\text{old}} \setminus \{d\}$ is defined as follows:

$$(5.3.6.1) \quad a \in B : \Leftrightarrow (\forall v \in V: a \approx_v d).$$

Suppose alternative d is replaced by the set of alternatives K in such a manner that (4.7.1) – (4.7.3) are satisfied.

Then:

$$(5.3.6.2) \quad \forall O_1 \in \mathcal{LO}_{A^{\text{old}}} \forall g \in K:$$

$$\begin{aligned} p^{\text{old}}[O_1] &= \sum (p^{\text{new}}[O] \mid O \in \mathcal{LO}_{A^{\text{new}}} \text{ with} \\ (1) \quad &\forall a, b \in A^{\text{new}} \setminus K: ab \in O_1 \Leftrightarrow ab \in O. \\ (2) \quad &\forall a \in A^{\text{new}} \setminus K: ad \in O_1 \Leftrightarrow ag \in O. \\ (3) \quad &\forall b \in A^{\text{new}} \setminus K: db \in O_1 \Leftrightarrow gb \in O.) \end{aligned}$$

$$(5.3.6.3) \quad \forall a, b \in A^{\text{new}} \setminus K: q^{\text{old}}[a, b] = q^{\text{new}}[a, b].$$

$$(5.3.6.4) \quad \forall a \in A^{\text{new}} \setminus K \forall g \in K: q^{\text{old}}[a, d] = q^{\text{new}}[a, g].$$

$$(5.3.6.5) \quad \forall b \in A^{\text{new}} \setminus K \forall g \in K: q^{\text{old}}[d, b] = q^{\text{new}}[g, b].$$

$$(5.3.6.6) \quad \forall a \in A^{\text{new}} \setminus K:$$

$$(i) \quad (a \notin B) \Rightarrow (r^{\text{old}}[a] = r^{\text{new}}[a]).$$

$$(ii) \quad (a \in B) \Rightarrow (r^{\text{old}}[a] \cdot (1 + \|B\|) = r^{\text{new}}[a] \cdot (\|K\| + \|B\|)).$$

$$(5.3.6.7) \quad (i) \quad (B = \emptyset) \Rightarrow (r^{\text{old}}[d] = \sum (r^{\text{new}}[g] \mid g \in K)).$$

$$(ii) \quad (B \neq \emptyset) \Rightarrow \forall g \in K: (r^{\text{old}}[d] \cdot (1 + \|B\|) = r^{\text{new}}[g] \cdot (\|K\| + \|B\|)).$$

$$(5.3.6.8) \quad \forall O_1 \in \mathcal{LO}_K:$$

$$p[O_1]_K = \sum (p^{\text{new}}[O] \mid O \in \mathcal{LO}_{A^{\text{new}}} \text{ with } O_1 \subseteq O).$$

$$(5.3.6.9) \quad \forall g, h \in K: q[g, h]_K = q^{\text{new}}[g, h].$$

$$(5.3.6.10) \quad \forall \emptyset \neq K_1 \subseteq K:$$

$$\text{Suppose } X := \sum (r[g]_K \mid g \in K_1).$$

$$\text{Suppose } Y := \sum (r^{\text{new}}[g] \mid g \in K_1).$$

$$\text{Suppose } B = \emptyset.$$

Then we get:

$$\max \{ 0, r^{\text{old}}[d] + X - 1 \} \leq Y \leq \min \{ r^{\text{old}}[d], X \}.$$

Claim:

The Schulze method $O_{final}(\sigma)$, as defined in sections 5.1, is independent of clones.

Proof (overview):

The proof for (5.3.6.2) – (5.3.6.7) is identical to the proof for (4.7.4) – (4.7.8) in section 4.7. (5.3.6.8) – (5.3.6.10) follows directly from section 5.1 Step 2(b).

5.3.7. Smith

Definition:

An election method satisfies *Smith* if the following holds:

Suppose (4.8.2) and (4.8.3).

Then we get:

$$(5.3.7.1) \quad \forall a \in B_1 \forall b \in B_2: q[a,b] = 1.$$

$$(5.3.7.2) \quad \sum (r[a] \mid a \in B_1) = 1.$$

An election method satisfies *Smith-IIA* if the following holds:

Suppose (4.8.2) and (4.8.3).

Suppose $d \in B_2$ is removed. Then we get:

$$(5.3.7.3) \quad \forall O_1 \in \mathcal{LO}_{B_1}: \\ \sum (p^{\text{old}}[O] \mid O \in \mathcal{LO}_A \text{ with } O_1 \subset O) = \\ \sum (p^{\text{new}}[O] \mid O \in \mathcal{LO}_{(A \setminus \{d\})} \text{ with } O_1 \subset O).$$

$$(5.3.7.4) \quad \forall a,b \in B_1: q^{\text{old}}[a,b] = q^{\text{new}}[a,b].$$

$$(5.3.7.5) \quad \forall a \in B_1: r^{\text{old}}[a] = r^{\text{new}}[a].$$

Suppose $d \in B_1$ is removed. Then we get:

$$(5.3.7.6) \quad \forall O_1 \in \mathcal{LO}_{B_2}: \\ \sum (p^{\text{old}}[O] \mid O \in \mathcal{LO}_A \text{ with } O_1 \subset O) = \\ \sum (p^{\text{new}}[O] \mid O \in \mathcal{LO}_{(A \setminus \{d\})} \text{ with } O_1 \subset O).$$

$$(5.3.7.7) \quad \forall a,b \in B_2: q^{\text{old}}[a,b] = q^{\text{new}}[a,b].$$

Claim:

If $>_D$ satisfies (2.1.5), then the Schulze method $O_{final}(\sigma)$, as defined in sections 5.1, satisfies Smith and Smith-IIA.

Proof (overview):

The proof is identical to the proofs in section 4.8.

In the probabilic framework, *participation* says that, when we have (4.8.2), (4.8.21), and (4.8.22), then we get:

$$(5.3.7.8) \quad \forall e \in B_1 \forall f \in B_2: q^{\text{old}}[e, f] \leq q^{\text{new}}[e, f].$$

$$(5.3.7.9) \quad \sum (r^{\text{old}}[e] \mid e \in B_1) \leq \sum (r^{\text{new}}[e] \mid e \in B_1).$$

Example 7 (section 3.7) can be used to show a violation of the probabilistic version of the participation criterion.

5.3.8. Runtime

The runtime to calculate the pairwise matrix is $O(N \cdot (C^2))$.

The runtime to calculate the TBRL $>_{\sigma}$, as defined in section 5.1 step 2, is $O(N \cdot (C^4))$ because, in worst case, $O(N)$ ballots have to be picked and, each time, $O(C^2)$ links are compared with $O(C^2)$ other links.

On closer examination, to sort the $O(C^2)$ links according to their strengths, it is not necessary to compare each of the $O(C^2)$ links with each other of the $O(C^2)$ links directly. As the fastest algorithms to sort X items according to their strengths have a runtime of $O(X \cdot \log(X))$, the runtime of the fastest algorithms to sort the $O(C^2)$ links according to their strengths is $O((C^2) \cdot \log(C))$.

Therefore, the runtime to calculate the TBRL $>_{\sigma}$, as defined in section 5.1 step 2, reduces to $O(N \cdot (C^2) \cdot \log(C))$.

The runtime to calculate the binary relation $O_{\text{final}}(\sigma)$, as defined in section 5.1 step 4, is $O(C^7)$ because, in worst case, there are $O(C^2)$ pairwise ties “ $P_{\sigma}[m, n] \approx_{\sigma} P_{\sigma}[n, m]$ ” (line 54). In worst case, $O(C^2)$ links have to be declared *forbidden* to resolve a pairwise tie. Each time, the runtime of the Floyd-Warshall algorithm to calculate the strength of the strongest path from every alternative to every other alternative is $O(C^3)$.

On closer examination, to resolve the pairwise tie “ $P_{\sigma}[m, n] \approx_{\sigma} P_{\sigma}[n, m]$ ”, it is not necessary to calculate the strength of the strongest path from every alternative to every other alternative. It is sufficient to calculate the strength of the strongest path from alternative m to alternative n and the strength of the strongest path from alternative n to alternative m . This can be done with the Dijkstra algorithm in a runtime $O(C^2)$.

Therefore, the runtime to calculate the binary relation $O_{\text{final}}(\sigma)$, as defined in section 5.1 step 4, reduces to $O(C^6)$.

Thus, the total runtime to calculate the binary relation $O_{\text{final}}(\sigma)$, as defined in section 5.1, is $O((N \cdot (C^2) \cdot \log(C)) + (C^6))$.

6. Supermajority Requirements

When preferential ballots are being used in referendums, then sometimes alternatives have to fulfill some supermajority requirements to qualify. Typical supermajority requirements define some $M_1 \in \mathbb{N}$ or some $1 \leq M_2 \in \mathbb{R}$ and say that $N[a,b]$ must be strictly larger than $\max \{ N[b,a], M_1 \}$ or that $N[a,b]$ must be strictly larger than $M_2 \cdot N[b,a]$ to replace alternative $b \in A$ by alternative $a \in A$. Or they say that $N[a,b]$ must be strictly larger than $N[b,a]$ not only in the electorate as a whole, but also in a majority of its geographic parts or even in each of its geographic parts. It is also possible that in the same referendum the voters have to choose between alternatives that have to fulfill different supermajority requirements to qualify. In this section, we discuss a possible way to combine the Schulze method with supermajority requirements. Suppose $s \in A$ is the *status quo*.

These are the two tasks of supermajority requirements:

Task #1 (*protecting the status quo*):

Supermajority requirements protect the status quo from accidental majorities. They make it more difficult to replace the status quo s by alternative $a \in A \setminus \{s\}$. Therefore, an important property of all supermajority requirements is that, when s had won in the absence of these requirements, then it also wins in the presence of these requirements.

Task #2 (*preventing the status quo from cycling*):

Supermajority requirements prevent the status quo from cycling. Suppose $s(0)$ is the starting status quo. Suppose $s(k+1)$ is the new status quo when the method is applied to the same set of alternatives A , to the same set of ballots V , and to the status quo $s(k)$. Then we would expect that (for every possible set of alternatives A , for every possible set of ballots V , and for every possible starting status quo $s(0) \in A$) there is an $m < C$ such that $s(k) \equiv s(m)$ for all $k \geq m$.

We recommend the following method:

The Schulze relation O , as defined in section 2.2, and the Schulze relation $O_{final}(\sigma)$, as defined in section 5.1, are calculated.

Alternative $a \in A \setminus \{s\}$ is *attainable* if and only if $N[a,s] > N[s,a]$ and (a) there is no supermajority requirement to replace the status quo s by alternative a or (b) alternative a has the supermajority required to replace the status quo s by alternative a .

Alternative $a \in A$ is *eligible* if and only if ($a \equiv s$) or ((a is attainable) and ($as \in O$)).

A winner is an alternative $a \in A$ with (1) alternative a is eligible and (2) $ab \in O_{final}(\sigma)$ for every other eligible alternative b .

The condition “ $as \in O$ ” in the definition of eligibility implies that alternative a can win only if it had disqualified the status quo s in the absence of supermajority requirements. This guarantees that, if s had won in the absence of supermajority requirements, then s also wins in the presence of these supermajority requirements.

In the above suggestion, the status quo s can only be replaced by an alternative a with $as \in O$. As O is transitive, it is guaranteed that the status quo cannot be changed in a cyclic manner.

Section 6 is also discussed by Behrens (2014b).

7. Electoral College

There has been some debate about how to combine the Schulze method with the Electoral College for the elections of the President of the USA. In my opinion, the Electoral College serves two important purposes:

Purpose #1: The Electoral College gives more power to the smaller states.

The Senate, where each state has the same voting power regardless of its population, is more powerful than the House of Representatives, where each state has a voting power in proportion of its population. This is true especially for decisions that are close to the executive. For example, the President needs the consent of the Senate for treaties and for the appointment of officers and judges. Because of this reason, it is more important that the President has a reliable support in the Senate than that he has a reliable support in the House of Representatives.

Purpose #2: The Electoral College makes it possible to count the ballots on the state levels and then to add up the electoral votes.

The Electoral College makes it possible that, to guarantee that all voters are treated in an equal manner, it is only necessary to guarantee that all voters *in the same state* are treated in an equal manner. However, if the ballots were added up on the national level, it would be necessary to guarantee that *all voters all over the USA* are treated in an equal manner. In the latter case, many provisions (e.g. the rules to gain suffrage or to be excluded from suffrage, the ballot access rules, the rules for postal voting, the opening hours of the polling places) would have to be harmonized all over the USA, leading to a very powerful central election authority.

This property is desirable especially for the elections to the National Conventions for the nominations of the presidential candidates. Here, the election rules and the set of candidates differ significantly from state to state.

To combine the Schulze method with the Electoral College without losing any of its purposes, we recommend that, for each pair of candidates a and b separately, we should determine how many electoral votes $N_{electors}[a,b]$ candidate a would get and how many electoral votes $N_{electors}[b,a]$ candidate b

would get when only these two candidates were running. We then apply the Schulze method to the matrix $N_{electors}$.

So we recommend the following method:

Stage 1:

Suppose A is the set of candidates who are running in at least one state.

Suppose $A_X \subseteq A$ is the set of candidates who are running in state X .

For $a, b \in A_X$: $N_X[a, b] \in \mathbb{N}_0$ is the number of voters in state X who strictly prefer candidate a to candidate b .

Stage 2:

Suppose $y \in \mathbb{R}$ with $y > 0$. Then “smaller_or_equal(y)” is the largest integer that is smaller than or equal to y . In other words: “smaller_or_equal(y)” is that integer $z \in \mathbb{N}_0$ with $z \leq y < (z + 1)$.

Suppose $y \in \mathbb{R}$ with $y > 0$. Then “strictly_smaller(y)” is the largest integer that is strictly smaller than y . In other words: “strictly_smaller(y)” is that integer $z \in \mathbb{N}_0$ with $z < y \leq (z + 1)$.

Suppose $E_X \in \mathbb{N}$ is the number of electors of state X .

Suppose:

- (a) $F_X[a, b] := E_X$,
if $\{ a \in A_X \text{ and } b \notin A_X \}$ or $\{ a, b \in A_X \text{ and } N_X[a, b] > N_X[b, a] = 0 \}$.
- (b) $F_X[a, b] := 0$,
if $\{ a \notin A_X \text{ and } b \in A_X \}$ or $\{ a, b \in A_X \text{ and } N_X[b, a] > N_X[a, b] = 0 \}$.
- (c) $F_X[a, b] := E_X / 2$,
if $\{ a, b \notin A_X \}$ or $\{ a, b \in A_X \text{ and } N_X[a, b] = N_X[b, a] \}$.
- (d) $F_X[a, b] := 0.01 \cdot \text{smaller\_or\_equal} \left(\frac{N_X[a, b] \cdot (1 + 100 \cdot E_X)}{N_X[a, b] + N_X[b, a]} \right)$,
if $a, b \in A_X$ and $N_X[a, b] > N_X[b, a] > 0$.
- (e) $F_X[a, b] := 0.01 \cdot \text{strictly\_smaller} \left(\frac{N_X[a, b] \cdot (1 + 100 \cdot E_X)}{N_X[a, b] + N_X[b, a]} \right)$,
if $a, b \in A_X$ and $N_X[b, a] > N_X[a, b] > 0$.

$$N_{electors}[a, b] := \sum_X F_X[a, b].$$

Stage 3:

The Schulze method, as defined in section 2.2, is applied to $N_{electors}$.

Suppose the Schulze method is used for presidential primaries. Suppose some candidate g withdraws and doesn’t take part in the remaining primaries. Then candidate g is not removed from the pairwise matrix. Rather he is treated as described at stage 2 (a) – (c). This regulation is necessary because removing a loser can still change the winner.

Stage 2 (a) – (b) guarantees that it can never be advantageous for a candidate not to run in a state. Stage 2 (c) guarantees that, when neither candidate a nor candidate b is running in a state, then $N_{electors}[a,b] - N_{electors}[b,a]$ doesn’t change.

Stage 2 (a) – (e) guarantees that, for every state X , we get

$$(7.1) \quad \forall a, b \in A: \quad 0 \leq F_X[a, b] \leq E_X.$$

$$(7.2) \quad \forall a, b \in A: \quad F_X[a, b] + F_X[b, a] = E_X.$$

So the weight of each state X in each pairwise contest is given by E_X .

8. Proportional Representation by the Single Transferable Vote

The term “Proportional Representation by the Single Transferable Vote” (STV) refers to preferential multi-winner election methods where the winning alternatives represent the electorate in a proportional manner. What exactly “in a proportional manner” means in this context is debatable and will be discussed in section 8.4.

A is a finite and non-empty set of alternatives. $M \in \mathbb{N}$ with $0 < M < \infty$ is the number of seats. $C \in \mathbb{N}$ with $M < C < \infty$ is the number of alternatives. $N \in \mathbb{N}$ with $0 < N < \infty$ is the number of voters.

A_M is the set of the $(C!)/((M!) \cdot ((C-M)!))$ possible ways to choose M different alternatives from the set A . The elements of A_M are indicated with *wedding* letters $\mathfrak{A}, \mathfrak{B}, \mathfrak{C}, \dots$

Input of an STV method is a profile, as defined in section 2.1. Output of an STV method is a subset $\emptyset \neq \mathcal{S}_M \subseteq A_M$ of potential winning sets.

8.1. Schulze STV

In Schulze STV, we only compare every set of M alternatives with every other set of M alternatives that differs in exactly one alternative.

There are $(C!)/((M!) \cdot (C-M)!)$ sets of exactly M alternatives.

There are $(C!)/(((M+1)!) \cdot ((C-M-1)!))$ possible $(M+1)$ -way contests. Each $(M+1)$ -way contest leads to $M \cdot (M+1)$ links in that digraph where each node represents a set of M alternatives. See e.g. page 414.

So we have a digraph with $(C!)/((M!)\cdot(C-M)!)$ nodes and $M\cdot(M+1)\cdot(C!)/(((M+1)!)\cdot((C-M-1)!)) = (C!)/(((M-1)!)\cdot((C-M-1)!))$ links. This digraph is strongly connected. (A digraph is *strongly connected* : $\Leftrightarrow$ For every pair of two different nodes $\mathcal{A}$ and $\mathcal{B}$, there is a directed path from node $\mathcal{A}$ to node $\mathcal{B}$ and a directed path from node $\mathcal{B}$ to node $\mathcal{A}$.) We then apply the Schulze method, as defined in section 2.2, to this digraph. This works because, for the proof in section 4.1, it is sufficient that the digraph, that the Schulze method is applied to, is strongly connected. It is not necessary that this digraph is complete.

Schulze STV is motivated by the fact that we want a generalization of the Condorcet criterion from single-winner elections to multi-winner elections that is as strong as possible (section 8.3), so that the possibility, that an additional alternative changes the result of the election without being elected, is minimized. In section 8.4, we will see that the Condorcet criterion, that we get by this manner, is so strong that we almost always have M Condorcet winners or, at least, $(M-1)$ Condorcet winners.

Like in section 2, two degrees of freedom have to be addressed: (1) How is the strength $(a_1; \dots; a_{(M-1)}; b; c)$ of the link $(a_1; \dots; a_{(M-1)}; b) \rightarrow (a_1; \dots; a_{(M-1)}; c)$ measured? (2) How do we solve situations without a unique winning set?

Suppose $\mathcal{U} := \{u_1, \dots, u_N\}$ is a list of N strict weak orders each on the same set of $(M+1)$ alternatives $(a_1; \dots; a_{(M-1)}; b; c)$. Suppose $\mathcal{V} := \{v_1, \dots, v_N\}$ is a list of N strict weak orders each on the same set of $(M+1)$ alternatives $(d_1; \dots; d_{(M-1)}; e; f)$. Then, we presume that $\succ_D$ is a strict weak order that compares $\mathcal{U}$ and $\mathcal{V}$. We presume that $\succ_D$ satisfies at least the following presumptions:

$$(8.1.1) \quad (\text{independence of permutating } a_1, \dots, a_{(M-1)})$$

Suppose the alternatives in $a_1, \dots, a_{(M-1)}$ are permuted. Then we get: $\mathcal{U}^{\text{old}} \approx_D \mathcal{U}^{\text{new}}$.

Presumption (8.1.1) allows us to write $(\{a_1, \dots, a_{(M-1)}\}; b; c)$, instead of $(a_1; \dots; a_{(M-1)}; b; c)$, for the strength of the link $(\{a_1, \dots, a_{(M-1)}\}; b) \rightarrow (\{a_1, \dots, a_{(M-1)}\}; c)$.

$$(8.1.2) \quad (\text{anonymity})$$

Suppose $\{\tau(1), \dots, \tau(N)\}$ is a permutation of $\{1, \dots, N\}$. Then for every list $\mathcal{U} := \{u_1, \dots, u_N\}$ of N elements, we get

$$\{u_{\tau(1)}, \dots, u_{\tau(N)}\} \approx_D \{u_1, \dots, u_N\}.$$

(8.1.3) *(independence of empty ballots)*

Suppose an empty ballot (i.e. a ballot that is indifferent between all alternatives $a_1, \dots, a_{(M-1)}, b, c$ resp. between all alternatives $d_1, \dots, d_{(M-1)}, e, f$) is added at the end of $\mathcal{U}$ and $\mathcal{V}$. Then we get

$$\mathcal{U}^{\text{old}} \succ_D \mathcal{V}^{\text{old}} \Leftrightarrow \mathcal{U}^{\text{new}} \succ_D \mathcal{V}^{\text{new}}.$$

(8.1.4) *(non-negative responsiveness)*

Suppose some ballots in $\mathcal{U} := \{u_1, \dots, u_N\}$ are replaced by ballots where alternative b is ranked higher and/or where alternative c is ranked lower without changing the order in which the other alternatives $a_1, \dots, a_{(M-1)}$ are ranked relatively to each other. Then the strength of $\mathcal{U}$ must not decrease.

Suppose

$$(8.1.4a) \quad \forall v \in \mathcal{U} \forall a_i, a_j \in a_1, \dots, a_{(M-1)}: a_i \succ_v^{\text{old}} a_j \Leftrightarrow a_i \succ_v^{\text{new}} a_j.$$

$$(8.1.4b) \quad \forall v \in \mathcal{U} \forall a_i \in a_1, \dots, a_{(M-1)}: b \succ_v^{\text{old}} a_i \Rightarrow b \succ_v^{\text{new}} a_i.$$

$$(8.1.4c) \quad \forall v \in \mathcal{U} \forall a_i \in a_1, \dots, a_{(M-1)}: b \approx_v^{\text{old}} a_i \Rightarrow b \approx_v^{\text{new}} a_i.$$

$$(8.1.4d) \quad \forall v \in \mathcal{U} \forall a_i \in a_1, \dots, a_{(M-1)}: a_i \succ_v^{\text{old}} c \Rightarrow a_i \succ_v^{\text{new}} c.$$

$$(8.1.4e) \quad \forall v \in \mathcal{U} \forall a_i \in a_1, \dots, a_{(M-1)}: a_i \approx_v^{\text{old}} c \Rightarrow a_i \approx_v^{\text{new}} c.$$

$$(8.1.4f) \quad \forall v \in \mathcal{U}: b \succ_v^{\text{old}} c \Rightarrow b \succ_v^{\text{new}} c.$$

$$(8.1.4g) \quad \forall v \in \mathcal{U}: b \approx_v^{\text{old}} c \Rightarrow b \approx_v^{\text{new}} c.$$

Then: $\mathcal{U}^{\text{old}} \approx_D \mathcal{U}^{\text{new}}$.

(8.1.5) *(positive responsiveness)*

Suppose (8.1.4a) – (8.1.4g).

Suppose

$$(8.1.5a) \quad \exists v \in \mathcal{U}: (b <_v^{\text{old}} c \wedge b >_v^{\text{new}} c).$$

Suppose

$$(8.1.5b) \quad \forall a_i \in a_1, \dots, a_{(M-1)} \exists v \in \mathcal{U}: (b <_v^{\text{old}} a_i \wedge b >_v^{\text{new}} a_i).$$

or

$$(8.1.5c) \quad \forall a_i \in a_1, \dots, a_{(M-1)} \exists v \in \mathcal{U}: (a_i <_v^{\text{old}} c \wedge a_i >_v^{\text{new}} c).$$

Then: $\mathcal{U}^{\text{old}} <_D \mathcal{U}^{\text{new}}$.

(8.1.6) *(reversal symmetry)*

Suppose the strength $(\{a_1, \dots, a_{(M-1)}\}; b; c)$ of the link $(\{a_1, \dots, a_{(M-1)}\}; b) \rightarrow (\{a_1, \dots, a_{(M-1)}\}; c)$ is stronger than the strength $(\{d_1, \dots, d_{(M-1)}\}; e; f)$ of the link $(\{d_1, \dots, d_{(M-1)}\}; e) \rightarrow (\{d_1, \dots, d_{(M-1)}\}; f)$. Then the strength $(\{d_1, \dots, d_{(M-1)}\}; f; e)$ of the link $(\{d_1, \dots, d_{(M-1)}\}; f) \rightarrow (\{d_1, \dots, d_{(M-1)}\}; e)$ is stronger than the strength $(\{a_1, \dots, a_{(M-1)}\}; c; b)$ of the link $(\{a_1, \dots, a_{(M-1)}\}; c) \rightarrow (\{a_1, \dots, a_{(M-1)}\}; b)$.

(8.1.7) *(homogeneity)*

For every $x_1, x_2 \in \mathbb{N}$, we get

$$\frac{x_1 \text{ times}}{\mathcal{U} + \dots + \mathcal{U}} >_D \frac{x_1 \text{ times}}{\mathcal{V} + \dots + \mathcal{V}} \Rightarrow \frac{x_2 \text{ times}}{\mathcal{U} + \dots + \mathcal{U}} >_D \frac{x_2 \text{ times}}{\mathcal{V} + \dots + \mathcal{V}}.$$

(8.1.8) *(independence of strong winners)*

Suppose that some voters change the order in which they rank the alternatives $a_1, \dots, a_{(M-1)}$ relatively to each other. Suppose we have

$$(8.1.8a) \quad \forall v \in \mathcal{U} \forall a_i \in a_1, \dots, a_{(M-1)}: a_i >_v^{\text{old}} b \Leftrightarrow a_i >_v^{\text{new}} b.$$

$$(8.1.8b) \quad \forall v \in \mathcal{U} \forall a_i \in a_1, \dots, a_{(M-1)}: b >_v^{\text{old}} a_i \Leftrightarrow b >_v^{\text{new}} a_i.$$

$$(8.1.8c) \quad \forall v \in \mathcal{U} \forall a_i \in a_1, \dots, a_{(M-1)}: a_i >_v^{\text{old}} c \Leftrightarrow a_i >_v^{\text{new}} c.$$

$$(8.1.8d) \quad \forall v \in \mathcal{U} \forall a_i \in a_1, \dots, a_{(M-1)}: c >_v^{\text{old}} a_i \Leftrightarrow c >_v^{\text{new}} a_i.$$

$$(8.1.8e) \quad \forall v \in \mathcal{U}: b >_v^{\text{old}} c \Leftrightarrow b >_v^{\text{new}} c.$$

$$(8.1.8f) \quad \forall v \in \mathcal{U}: c >_v^{\text{old}} b \Leftrightarrow c >_v^{\text{new}} b.$$

Then we get: $\mathcal{U}^{\text{old}} \approx_D \mathcal{U}^{\text{new}}$.

 (8.1.9) *(transitivity and negative transitivity
in the M-seat (M+1)-alternative case)*

(a) Suppose $(\{a_1, \dots, a_{(M-2)}, z\}; x; y) >_D (\{a_1, \dots, a_{(M-2)}, z\}; y; x)$ and $(\{a_1, \dots, a_{(M-2)}, x\}; y; z) >_D (\{a_1, \dots, a_{(M-2)}, x\}; z; y)$. Then we get: $(\{a_1, \dots, a_{(M-2)}, y\}; x; z) >_D (\{a_1, \dots, a_{(M-2)}, y\}; z; x)$.

(b) Suppose $(\{a_1, \dots, a_{(M-2)}, z\}; x; y) \approx_D (\{a_1, \dots, a_{(M-2)}, z\}; y; x)$ and $(\{a_1, \dots, a_{(M-2)}, x\}; y; z) \approx_D (\{a_1, \dots, a_{(M-2)}, x\}; z; y)$. Then we get: $(\{a_1, \dots, a_{(M-2)}, y\}; x; z) \approx_D (\{a_1, \dots, a_{(M-2)}, y\}; z; x)$.

(c) Suppose $(\{a_1, \dots, a_{(M-2)}, z\}; x; y) \approx_D (\{a_1, \dots, a_{(M-2)}, z\}; y; x)$ and $(\{a_1, \dots, a_{(M-2)}, x\}; y; z) \approx_D (\{a_1, \dots, a_{(M-2)}, x\}; z; y)$. Then we get: $(\{a_1, \dots, a_{(M-2)}, y\}; x; z) \approx_D \max_D \{(\{a_1, \dots, a_{(M-2)}, z\}; x; y), (\{a_1, \dots, a_{(M-2)}, x\}; y; z)\}$.

(d) Suppose $(\{a_1, \dots, a_{(M-2)}, z\}; x; y) \lesssim_D (\{a_1, \dots, a_{(M-2)}, z\}; y; x)$ and $(\{a_1, \dots, a_{(M-2)}, x\}; y; z) \lesssim_D (\{a_1, \dots, a_{(M-2)}, x\}; z; y)$. Then we get: $(\{a_1, \dots, a_{(M-2)}, y\}; x; z) \lesssim_D \min_D \{(\{a_1, \dots, a_{(M-2)}, z\}; x; y), (\{a_1, \dots, a_{(M-2)}, x\}; y; z)\}$.

The importance of the presumptions (8.1.1) – (8.1.7) follows directly from the considerations in sections 2 – 5.

Presumption (8.1.8) is motivated by the considerations in Schulze (2004, 2011b): In multi-winner elections, but not in single-winner elections, it is a useful strategy for a voter not to give a good preference to an alternative that wins with certainty even without this voter’s vote (*Hylland free riding*). By using this strategy, this voter increases his impact on which the other winners are. When the voters have understood this strategic loophole well, the order in which the individual voter ranks the strong alternatives relatively to each other doesn’t say anything anymore about the sincere opinion of this voter, but only about his strategic skills and his information about the opinions of the other voters. So the order, in which the individual voter ranks the strong alternatives relatively to each other, doesn’t contain any information and should, therefore, have no impact on the result of the election.

Presumption (8.1.9) says that, at least in the M -seat $(M+1)$ -alternative case, pairwise comparisons must be transitive [presumption (8.1.9)(a)] and negatively transitive [presumption (8.1.9)(b)] so that, at least in this case, the result cannot be cyclic.

In sections 8.1.1 and 8.1.2, we will introduce a concrete definition for the strength of links that satisfies (8.1.1) – (8.1.9). In section 8.1.3, we will describe how Schulze STV will look like with this definition for the strength of links.

8.1.1. Proportional Completion

Proportional completion means that non-linear individual orders are completed to linear orders in such a manner that, for each set of alternatives, the proportions of the individual orders, restricted to these alternatives, are not changed.

Example: Suppose a voter is indifferent between alternative a and alternative b . Suppose of the other voters $X_1 = 56$ strictly prefer alternative a to alternative b and $X_2 = 44$ strictly prefer alternative b to alternative a , then this voter is replaced by $X_1/(X_1+X_2) = 0.56$ voters who rank these alternatives $a >_v b$ and by $X_2/(X_1+X_2) = 0.44$ voters who rank these alternatives $b >_v a$ and who rank the other alternatives in the same manner as the original voter did.

Basic idea behind proportional completion is that, on the one side, adding a voter who is indifferent between all alternatives, that have chances to win, should not change the result of the election as this additional voter doesn’t add new information. On the other side, the definition for the strengths of the links between sets of alternatives (section 8.1.2) requires that each voter casts a linear order.

The following 3 stages give a precise definition for proportional completion.

Stage 1:

W shall be the proportional completion of V . $\rho(w) \in \mathbb{R}$ shall be the weight of voter $w \in W$. Then we start with

$$(8.1.1.1) \quad W := V.$$

$$(8.1.1.2) \quad \forall w \in W: \rho(w) := 1.$$

Stage 2:

Suppose there is a voter $w \in W$ and a set of alternatives $f_1, \dots, f_n \in A$ with

$$(8.1.1.3) \quad n > 1.$$

$$(8.1.1.4) \quad \forall f_i, f_j \in \{f_1, \dots, f_n\}: f_i \approx_w f_j.$$

$$(8.1.1.5) \quad \forall f_i \in \{f_1, \dots, f_n\} \forall e \in A \setminus \{f_1, \dots, f_n\}: f_i \not\approx_w e.$$

Suppose $X \in \mathbb{N}_0$ is the number of voters $v \in V$ with

$$(8.1.1.6) \quad \exists f_i, f_j \in \{f_1, \dots, f_n\}: f_i \not\approx_v f_j.$$

Case 1: $X > 0$.

For each voter $v \in V$ with (8.1.1.6), a voter u is added to W with

$$(8.1.1.7) \quad \forall g, h \in A \setminus \{f_1, \dots, f_n\}: g \succ_w h \Leftrightarrow g \succ_u h.$$

$$(8.1.1.8) \quad \forall f_i \in \{f_1, \dots, f_n\} \forall g \in A \setminus \{f_1, \dots, f_n\}: g \succ_w f_i \Leftrightarrow g \succ_u f_i.$$

$$(8.1.1.9) \quad \forall f_i \in \{f_1, \dots, f_n\} \forall h \in A \setminus \{f_1, \dots, f_n\}: f_i \succ_w h \Leftrightarrow f_i \succ_u h.$$

$$(8.1.1.10) \quad \forall f_i, f_j \in \{f_1, \dots, f_n\}: f_i \succ_v f_j \Leftrightarrow f_i \succ_u f_j.$$

$$(8.1.1.11) \quad \rho(u) := \rho(w) / X.$$

Case 2: $X = 0$.

For each of the $n!$ possible permutations $\{\tau(1), \dots, \tau(n)\}$ of $\{1, \dots, n\}$, a voter u is added to W with (8.1.1.7) – (8.1.1.9) and

$$(8.1.1.12) \quad \forall f_i, f_j \in \{f_1, \dots, f_n\}: \tau(i) > \tau(j) \Leftrightarrow f_i \succ_u f_j.$$

$$(8.1.1.13) \quad \rho(u) := \rho(w) / (n!).$$

After all these voters u have been added to W , the original voter w is removed from W .

Stage 3:

Stage 2 is repeated until $a \not\approx_w b \forall a \in A \forall b \in A \setminus \{a\} \forall w \in W$.

So in each iteration of proportional completion, we look whether there is still a voter who casts a non-linear order. When there is still such a voter, then we take a voter $w \in W$ and a set of alternatives $\emptyset \neq \{f_1, \dots, f_n\} \subseteq A$ (with $n > 1$) where voter w is indifferent between all the alternatives in $\{f_1, \dots, f_n\}$ [see (8.1.1.4)] and different between any alternative in $\{f_1, \dots, f_n\}$ and any alternative in $A \setminus \{f_1, \dots, f_n\}$ [see (8.1.1.5)]. We then look how those voters, who are not indifferent between all the alternatives in $\{f_1, \dots, f_n\}$ [see (8.1.1.6)], rank the alternatives in $\{f_1, \dots, f_n\}$. Voter w is then replaced, in a proportional manner [see (8.1.1.11)], by voters who rank the alternatives in $A \setminus \{f_1, \dots, f_n\}$ in the same order as voter w did [see (8.1.1.7) – (8.1.1.9)] and who rank the alternatives in $\{f_1, \dots, f_n\}$ in the same order as the other voters do [see (8.1.1.10)].

8.1.2. Links between Sets of Alternatives

In this section, we will propose a concrete definition for $>_D$ that satisfies (8.1.1) – (8.1.9).

Suppose $\{a_1, \dots, a_M, g\} \subset A$. We will define $N[\{a_1, \dots, a_M\}; g] \in \mathbb{R}_{\geq 0}$. We then get the *support* of the link $(\{a_1, \dots, a_{(M-1)}\}; b) \rightarrow (\{a_1, \dots, a_{(M-1)}\}; c)$ by replacing a_M by b and by replacing g by c in the definition of $N[\{a_1, \dots, a_M\}; g]$. We get the *opposition* of the link $(\{a_1, \dots, a_{(M-1)}\}; b) \rightarrow (\{a_1, \dots, a_{(M-1)}\}; c)$ by replacing a_M by c and by replacing g by b in the definition of $N[\{a_1, \dots, a_M\}; g]$.

The link $(\{a_1, \dots, a_{(M-1)}\}; b) \rightarrow (\{a_1, \dots, a_{(M-1)}\}; c)$ is then stronger than the link $(\{d_1, \dots, d_{(M-1)}\}; e) \rightarrow (\{d_1, \dots, d_{(M-1)}\}; f)$ if and only if

$$(N[\{a_1, \dots, a_{(M-1)}, b\}; c], N[\{a_1, \dots, a_{(M-1)}, c\}; b]) >_{D_2} (N[\{d_1, \dots, d_{(M-1)}, e\}; f], N[\{d_1, \dots, d_{(M-1)}, f\}; e])$$

where $>_{D_2}$ is a strict weak order on $\mathbb{R}_{\geq 0} \times \mathbb{R}_{\geq 0}$ that satisfies (2.1.1) – (2.1.3).

So we get

$$(8.1.2.1) \quad (\{a_1, \dots, a_{(M-1)}\}; b; c) >_D (\{d_1, \dots, d_{(M-1)}\}; e; f) : \Leftrightarrow (N[\{a_1, \dots, a_{(M-1)}, b\}; c], N[\{a_1, \dots, a_{(M-1)}, c\}; b]) >_{D_2} (N[\{d_1, \dots, d_{(M-1)}, e\}; f], N[\{d_1, \dots, d_{(M-1)}, f\}; e]).$$

Basic idea for the definition for the support $N[\{a_1, \dots, a_M\}; g]$ of the link $\{a_1, \dots, a_M\} \rightarrow (\{a_1, \dots, a_{(M-1)}\}; g)$ is that a defeat of alternative a against alternative g of strength $N[a, g]$ in a single-winner election corresponds to a situation where each of the alternatives $\{a_1, \dots, a_M\}$ has a “separate quota” against alternative g of strength $N[\{a_1, \dots, a_M\}; g]$ in an M -seat election. See (8.1.2.6) – (8.1.2.7).

W is the proportional completion of V . $\rho(w) \in \mathbb{R}$ is the weight of voter $w \in W$. N_W is the number of voters in W . Then the support $N[\{a_1, \dots, a_M\}; g] \in \mathbb{R}_{\geq 0}$ of the link from $\{a_1, \dots, a_M\}$ to $(\{a_1, \dots, a_{(M-1)}\}; g)$ is defined as follows:

$N[\{a_1, \dots, a_M\}; g] \in \mathbb{R}_{\geq 0}$ is the largest value such that there is a $t \in \mathbb{R}^{(N_W \times M)}$ such that

$$(8.1.2.2) \quad \forall i \in \{1, \dots, N_W\} \quad \forall j \in \{1, \dots, M\}: t_{ij} \geq 0.$$

$$(8.1.2.3) \quad \forall i \in \{1, \dots, N_W\}: \sum_{j=1}^M t_{ij} \leq \rho(i).$$

$$(8.1.2.4) \quad \forall i \in \{1, \dots, N_W\} \quad \forall j \in \{1, \dots, M\}: g >_i a_j \Rightarrow t_{ij} = 0.$$

$$(8.1.2.5) \quad \forall j \in \{1, \dots, M\}: \sum_{i=1}^{N_W} t_{ij} \geq N[\{a_1, \dots, a_M\}; g].$$

So the support $N[\{a_1, \dots, a_M\}; g] \in \mathbb{R}_{\geq 0}$ of the link $\{a_1, \dots, a_M\} \rightarrow (\{a_1, \dots, a_{(M-1)}\}; g)$ is the largest number such that the electorate can be divided into $M+1$ disjoint sets $T_1, \dots, T_{(M+1)}$ such that:

$$(8.1.2.6) \quad \forall j \in \{1, \dots, M\}: \text{Every voter in } T_j \text{ prefers alternative } a_j \text{ to alternative } g.$$

$$(8.1.2.7) \quad \forall j \in \{1, \dots, M\}: \text{The total weight of the voters in } T_j \text{ is at least } N[\{a_1, \dots, a_M\}; g].$$

8.1.3. Definition of Schulze STV

Proportional completion is defined in section 8.1.1. $N[\{a_1, \dots, a_M\}; g]$ is defined in section 8.1.2. $>_{D1}$ and $>_{D2}$ are two binary relations that each satisfy (2.1.1) – (2.1.3).

Stage 1:

We calculate a Schulze single-winner ranking $O_{final}(\sigma)$ on A , as defined in section 5.1, with $>_{D1}$.

Stage 2:

Proportional completion is used to complete V to W .

Stage 3:

A *path* from set $\mathcal{X} \in A_M$ to set $\mathcal{Y} \in A_M \setminus \{\mathcal{X}\}$ is a sequence of sets $\mathcal{U}(1), \dots, \mathcal{U}(n) \in A_M$ with the following properties:

1. $\mathcal{X} \equiv \mathcal{U}(1)$.
2. $\mathcal{Y} \equiv \mathcal{U}(n)$.
3. $n \in \mathbb{N}$ with $2 \leq n \leq (C!)/((M!) \cdot ((C-M)!))$.
4. For all $i, j \in \{1, \dots, n\}$: $i \neq j \Rightarrow \mathcal{U}(i) \in A_M \setminus \{\mathcal{U}(j)\}$.
5. For all $i = 1, \dots, (n-1)$: $\mathcal{U}(i)$ and $\mathcal{U}(i+1)$ differ in exactly one alternative. That means: $\|\mathcal{U}(i) \cap \mathcal{U}(i+1)\| = M - 1$ and $\|\mathcal{U}(i) \cup \mathcal{U}(i+1)\| = M + 1$.

The *strength* of the path $\mathcal{U}(1), \dots, \mathcal{U}(n)$ is

$$\min_{D2} \{ (N[\{a_1, \dots, a_{(M-1)}, b\}; c], N[\{a_1, \dots, a_{(M-1)}, c\}; b]) \\ \text{with } \{a_1, \dots, a_{(M-1)}\} := \mathcal{U}(i) \cap \mathcal{U}(i+1), \\ b := \mathcal{U}(i) \setminus \mathcal{U}(i+1), \text{ and } c := \mathcal{U}(i+1) \setminus \mathcal{U}(i) \\ | i = 1, \dots, (n-1) \}.$$

In other words: The strength of a path is the strength of its weakest link.

$$P_{D2}[\mathcal{A}, \mathcal{B}] := \max_{D2} \{ \\ \min_{D2} \{ (N[\{a_1, \dots, a_{(M-1)}, b\}; c], N[\{a_1, \dots, a_{(M-1)}, c\}; b]) \\ \text{with } \{a_1, \dots, a_{(M-1)}\} := \mathcal{U}(i) \cap \mathcal{U}(i+1), \\ b := \mathcal{U}(i) \setminus \mathcal{U}(i+1), \text{ and } c := \mathcal{U}(i+1) \setminus \mathcal{U}(i) \\ | i = 1, \dots, (n-1) \} \\ | \mathcal{U}(1), \dots, \mathcal{U}(n) \text{ is a path from set } \mathcal{A} \text{ to set } \mathcal{B} \}.$$

In other words: $P_{D2}[\mathcal{A}, \mathcal{B}] \in \mathbb{N}_0 \times \mathbb{N}_0$ is the strength of the strongest path from set $\mathcal{A} \in A_M$ to set $\mathcal{B} \in A_M \setminus \{\mathcal{A}\}$.

(8.1.3.1) The binary relation O_M on A_M is defined as follows:
 $\mathcal{A}\mathcal{B} \in O_M : \Leftrightarrow P_{D2}[\mathcal{A}, \mathcal{B}] >_{D2} P_{D2}[\mathcal{B}, \mathcal{A}].$

(8.1.3.2) $S_M := \{ \mathcal{A} \in A_M \mid \forall \mathcal{B} \in A_M \setminus \{\mathcal{A}\}: \mathcal{B}\mathcal{A} \notin O_M \}$ is the set of potential winning sets.

Stage 4:

For all $\mathcal{A}, \mathcal{B} \in \mathcal{S}_M$: Suppose there is an alternative $a \in \mathcal{A} \setminus \mathcal{B}$ with $ab \in O_{final}(\sigma)$ for every alternative $b \in \mathcal{B} \setminus \mathcal{A}$, then the set $\mathcal{A}$ *disqualifies* the set $\mathcal{B}$.

The winning set of Schulze STV is that set $\mathcal{A} \in \mathcal{S}_M$ that is not disqualified by some other set $\mathcal{B} \in \mathcal{S}_M$.

8.2. Example A53

To illustrate Schulze STV, we will use a rather large example because smaller examples usually don’t address all aspects of an STV election. We will use example A53 from Tideman’s database. This example is analysed in great detail by Tideman (2000). Example A53 consists of $V = 460$ voters and $C = 10$ alternatives running for $M = 4$ seats.

Example A53 is interesting because the Newland-Britton (1997) method, the Meek (1969, 1970; I.D. Hill, 1987) method, and the Warren (1994) method each find a different set of winners. The Newland-Britton method chooses a, b, g , and j . The Meek method chooses a, d, g , and j . The Warren method chooses a, f, g , and j .

Example A53 is described in the following table 8.2.1. For example, row 233 says that voter 233 gives a “1” to alternative b , a “2” to alternative c , a “3” to alternative d , a “4” to alternative a , and a “5” to alternative j . Voter 233 doesn’t rank any of the other alternatives.

Table 8.2.1 (part 4 of 4): Example A53

8.2.1. Proportional Completion

We apply proportional completion separately for the calculation of each link. The strength of the links $\{b,c,e,j\} \rightarrow \{a,c,e,j\}$, $\{b,c,e,j\} \rightarrow \{a,b,e,j\}$, $\{b,c,e,j\} \rightarrow \{a,b,c,j\}$, and $\{b,c,e,j\} \rightarrow \{a,b,c,e\}$ depends only on whether the individual voter strictly prefers the different candidates of the set $\{b,c,e,j\}$ to candidate a or strictly prefers candidate a to the different candidates of the set $\{b,c,e,j\}$ or is indifferent between the different candidates of the set $\{b,c,e,j\}$ and candidate a . Therefore, the fact, that we apply proportional completion for every link separately, means that only $3^C = 81$ possible voting patterns need to be considered. Table 8.2.1.1 lists these 81 possible voting patterns, where “1” means that a voter with this voting pattern strictly prefers this candidate to candidate a , a “2” means that this voter is indifferent between this candidate and candidate a , and a “3” means that this voter strictly prefers candidate a to this candidate.

Throughout section 8.2.1, w_j^i is the number of voters at stage j who are using voting pattern i .

Table 8.2.1.1: The 81 possible voting patterns

Step 1

At first, we determine which profile is used by how many voters. Table 8.2.1.2 lists, for every voting pattern, how many voters (column “number of voters”) and which voters (column “voters”) are using this voting pattern.

voting pattern	number of voters	b	c	e	j	voters
#1	$w_1^1 = 17$	1	1	1	1	32, 60, 62, 107, 140, 151, 178, 192, 234, 235, 253, 257, 267, 269, 271, 274, 278
#2	$w_1^2 = 2$	1	1	1	2	12, 384
#3	$w_1^3 = 3$	1	1	1	3	255, 258, 270
#4	$w_1^4 = 4$	1	1	2	1	65, 155, 261, 273
#5	$w_1^5 = 4$	1	1	2	2	109, 203, 336, 338
#7	$w_1^7 = 6$	1	1	3	1	59, 90, 166, 249, 348, 367
#9	$w_1^9 = 3$	1	1	3	3	77, 233, 272
#10	$w_1^{10} = 7$	1	2	1	1	11, 174, 189, 195, 239, 242, 260
#11	$w_1^{11} = 7$	1	2	1	2	85, 144, 237, 248, 262, 276, 368
#13	$w_1^{13} = 14$	1	2	2	1	24, 117, 232, 252, 259, 263, 268, 285, 350, 356, 359, 360, 362, 377
#14	$w_1^{14} = 7$	1	2	2	2	93, 105, 214, 221, 240, 339, 448

Table 8.2.1.2 (2 of 2): voting patterns is example A53

Step 2

Each time, when we apply proportional completion to a voting pattern, we apply it to a voting pattern, where the number of alternatives with a "2" is the maximum. As, in each stage, a voting pattern is replaced by voting patterns with smaller numbers of alternatives with a "2", it is guaranteed that those voting patterns, to which proportional completion has already been applied at earlier stages of the proportional completion procedure, cannot reappear at later stages.

So first, we apply proportional completion to voting pattern #41. Applying proportional completion to a voting pattern where voters are indifferent between all candidates simply means that the weight of every other voting pattern is multiplied by the same factor.

Therefore, we get:

voting pattern	number of voters	b	c	e	j
#1	$w_2^1 = (1 + w_1^{41} / (N - w_1^{41})) \cdot w_1^1 = 17.494407$	1	1	1	1
#2	$w_2^2 = (1 + w_1^{41} / (N - w_1^{41})) \cdot w_1^2 = 2.058166$	1	1	1	2
#3	$w_2^3 = (1 + w_1^{41} / (N - w_1^{41})) \cdot w_1^3 = 3.087248$	1	1	1	3
#4	$w_2^4 = (1 + w_1^{41} / (N - w_1^{41})) \cdot w_1^4 = 4.116331$	1	1	2	1
#5	$w_2^5 = (1 + w_1^{41} / (N - w_1^{41})) \cdot w_1^5 = 4.116331$	1	1	2	2
#7	$w_2^7 = (1 + w_1^{41} / (N - w_1^{41})) \cdot w_1^7 = 6.174497$	1	1	3	1
#9	$w_2^9 = (1 + w_1^{41} / (N - w_1^{41})) \cdot w_1^9 = 3.087248$	1	1	3	3
#10	$w_2^{10} = (1 + w_1^{41} / (N - w_1^{41})) \cdot w_1^{10} = 7.203579$	1	2	1	1
#11	$w_2^{11} = (1 + w_1^{41} / (N - w_1^{41})) \cdot w_1^{11} = 7.203579$	1	2	1	2
#13	$w_2^{13} = (1 + w_1^{41} / (N - w_1^{41})) \cdot w_1^{13} = 14.407159$	1	2	2	1
#14	$w_2^{14} = (1 + w_1^{41} / (N - w_1^{41})) \cdot w_1^{14} = 7.203579$	1	2	2	2
#19	$w_2^{19} = (1 + w_1^{41} / (N - w_1^{41})) \cdot w_1^{19} = 18.523490$	1	3	1	1
#21	$w_2^{21} = (1 + w_1^{41} / (N - w_1^{41})) \cdot w_1^{21} = 2.058166$	1	3	1	3
#25	$w_2^{25} = (1 + w_1^{41} / (N - w_1^{41})) \cdot w_1^{25} = 10.290828$	1	3	3	1
#27	$w_2^{27} = (1 + w_1^{41} / (N - w_1^{41})) \cdot w_1^{27} = 17.494407$	1	3	3	3
#28	$w_2^{28} = (1 + w_1^{41} / (N - w_1^{41})) \cdot w_1^{28} = 8.232662$	2	1	1	1
#29	$w_2^{29} = (1 + w_1^{41} / (N - w_1^{41})) \cdot w_1^{29} = 6.174497$	2	1	1	2
#31	$w_2^{31} = (1 + w_1^{41} / (N - w_1^{41})) \cdot w_1^{31} = 2.058166$	2	1	2	1
#32	$w_2^{32} = (1 + w_1^{41} / (N - w_1^{41})) \cdot w_1^{32} = 3.087248$	2	1	2	2
#37	$w_2^{37} = (1 + w_1^{41} / (N - w_1^{41})) \cdot w_1^{37} = 11.319911$	2	2	1	1
#38	$w_2^{38} = (1 + w_1^{41} / (N - w_1^{41})) \cdot w_1^{38} = 7.203579$	2	2	1	2
#40	$w_2^{40} = (1 + w_1^{41} / (N - w_1^{41})) \cdot w_1^{40} = 23.668904$	2	2	2	1
#55	$w_2^{55} = (1 + w_1^{41} / (N - w_1^{41})) \cdot w_1^{55} = 11.319911$	3	1	1	1
#57	$w_2^{57} = (1 + w_1^{41} / (N - w_1^{41})) \cdot w_1^{57} = 3.087248$	3	1	1	3
#61	$w_2^{61} = (1 + w_1^{41} / (N - w_1^{41})) \cdot w_1^{61} = 10.290828$	3	1	3	1
#63	$w_2^{63} = (1 + w_1^{41} / (N - w_1^{41})) \cdot w_1^{63} = 5.145414$	3	1	3	3
#73	$w_2^{73} = (1 + w_1^{41} / (N - w_1^{41})) \cdot w_1^{73} = 13.378076$	3	3	1	1
#75	$w_2^{75} = (1 + w_1^{41} / (N - w_1^{41})) \cdot w_1^{75} = 14.407159$	3	3	1	3
#79	$w_2^{79} = (1 + w_1^{41} / (N - w_1^{41})) \cdot w_1^{79} = 86.442953$	3	3	3	1
#81	$w_2^{81} = (1 + w_1^{41} / (N - w_1^{41})) \cdot w_1^{81} = 129.664430$	3	3	3	3
	460.000000				

Step 3

We now apply proportional completion to voting pattern #14. In voting pattern #14, the voters are indifferent between the alternatives in $\{a, c, e, j\}$. At stage 1, $Y := w_1^{14} + w_1^{41} = 20$ voters were indifferent between all the alternatives in $\{a, c, e, j\}$. The following $N - Y = 440$ voters were not indifferent between all the alternatives in $\{a, c, e, j\}$:

number of voters	c	e	j
$w_1^1 + w_1^{28} + w_1^{55} = 36$	1	1	1
$w_1^2 + w_1^{29} = 8$	1	1	2
$w_1^3 + w_1^{57} = 6$	1	1	3
$w_1^4 + w_1^{31} = 6$	1	2	1
$w_1^5 + w_1^{32} = 7$	1	2	2
$w_1^7 + w_1^{61} = 16$	1	3	1
$w_1^9 + w_1^{63} = 8$	1	3	3
$w_1^{10} + w_1^{37} = 18$	2	1	1
$w_1^{11} + w_1^{38} = 14$	2	1	2
$w_1^{13} + w_1^{40} = 37$	2	2	1
$w_1^{19} + w_1^{73} = 31$	3	1	1
$w_1^{21} + w_1^{75} = 16$	3	1	3
$w_1^{25} + w_1^{79} = 94$	3	3	1
$w_1^{27} + w_1^{81} = 143$	3	3	3
$N - Y = 440$			

Therefore, the $w_2^{14} = 7.203579$ voters with voting pattern #14 are replaced by the following voters:

voting pattern	number of voters	b	c	e	j
#1	$(w_1^1 + w_1^{28} + w_1^{55}) \cdot w_2^{14} / (N - Y) = 0.589384$	1	1	1	1
#2	$(w_1^2 + w_1^{29}) \cdot w_2^{14} / (N - Y) = 0.130974$	1	1	1	2
#3	$(w_1^3 + w_1^{57}) \cdot w_2^{14} / (N - Y) = 0.098231$	1	1	1	3
#4	$(w_1^4 + w_1^{31}) \cdot w_2^{14} / (N - Y) = 0.098231$	1	1	2	1
#5	$(w_1^5 + w_1^{32}) \cdot w_2^{14} / (N - Y) = 0.114602$	1	1	2	2
#7	$(w_1^7 + w_1^{61}) \cdot w_2^{14} / (N - Y) = 0.2619483$	1	1	3	1
#9	$(w_1^9 + w_1^{63}) \cdot w_2^{14} / (N - Y) = 0.130974$	1	1	3	3
#10	$(w_1^{10} + w_1^{37}) \cdot w_2^{14} / (N - Y) = 0.294692$	1	2	1	1
#11	$(w_1^{11} + w_1^{38}) \cdot w_2^{14} / (N - Y) = 0.229205$	1	2	1	2
#13	$(w_1^{13} + w_1^{40}) \cdot w_2^{14} / (N - Y) = 0.605756$	1	2	2	1
#19	$(w_1^{19} + w_1^{73}) \cdot w_2^{14} / (N - Y) = 0.507525$	1	3	1	1
#21	$(w_1^{21} + w_1^{75}) \cdot w_2^{14} / (N - Y) = 0.261948$	1	3	1	3
#25	$(w_1^{25} + w_1^{79}) \cdot w_2^{14} / (N - Y) = 1.538947$	1	3	3	1
#27	$(w_1^{27} + w_1^{81}) \cdot w_2^{14} / (N - Y) = 2.341163$	1	3	3	3
	$w_2^{14} = 7.203579$				

Therefore, we get:

voting pattern	number of voters	b	c	e	j
#1	$w_3^1 = w_2^1 + 0.589384 = 18.083791$	1	1	1	1
#2	$w_3^2 = w_2^2 + 0.130974 = 2.189140$	1	1	1	2
#3	$w_3^3 = w_2^3 + 0.098231 = 3.185479$	1	1	1	3
#4	$w_3^4 = w_2^4 + 0.098231 = 4.214562$	1	1	2	1
#5	$w_3^5 = w_2^5 + 0.114602 = 4.230933$	1	1	2	2
#7	$w_3^7 = w_2^7 + 0.261948 = 6.436445$	1	1	3	1
#9	$w_3^9 = w_2^9 + 0.130974 = 3.218222$	1	1	3	3
#10	$w_3^{10} = w_2^{10} + 0.294692 = 7.498271$	1	2	1	1
#11	$w_3^{11} = w_2^{11} + 0.229205 = 7.432784$	1	2	1	2
#13	$w_3^{13} = w_2^{13} + 0.605756 = 15.012914$	1	2	2	1
#19	$w_3^{19} = w_2^{19} + 0.507525 = 19.031015$	1	3	1	1
#21	$w_3^{21} = w_2^{21} + 0.261948 = 2.320114$	1	3	1	3
#25	$w_3^{25} = w_2^{25} + 1.538947 = 11.829774$	1	3	3	1
#27	$w_3^{27} = w_2^{27} + 2.341163 = 19.835570$	1	3	3	3
#28	$w_3^{28} = w_2^{28} = 8.232662$	2	1	1	1
#29	$w_3^{29} = w_2^{29} = 6.174497$	2	1	1	2
#31	$w_3^{31} = w_2^{31} = 2.058166$	2	1	2	1
#32	$w_3^{32} = w_2^{32} = 3.087248$	2	1	2	2
#37	$w_3^{37} = w_2^{37} = 11.319911$	2	2	1	1
#38	$w_3^{38} = w_2^{38} = 7.203579$	2	2	1	2
#40	$w_3^{40} = w_2^{40} = 23.668904$	2	2	2	1
#55	$w_3^{55} = w_2^{55} = 11.319911$	3	1	1	1
#57	$w_3^{57} = w_2^{57} = 3.087248$	3	1	1	3
#61	$w_3^{61} = w_2^{61} = 10.290828$	3	1	3	1
#63	$w_3^{63} = w_2^{63} = 5.145414$	3	1	3	3
#73	$w_3^{73} = w_2^{73} = 13.378076$	3	3	1	1
#75	$w_3^{75} = w_2^{75} = 14.407159$	3	3	1	3
#79	$w_3^{79} = w_2^{79} = 86.442953$	3	3	3	1
#81	$w_3^{81} = w_2^{81} = 129.664430$	3	3	3	3
	460.000000				

Step 4

We now apply proportional completion to voting pattern #32. In voting pattern #32, the voters are indifferent between the alternatives in $\{a, b, e, j\}$. At stage 1, $Y := w_1^{32} + w_1^{41} = 16$ voters were indifferent between all the alternatives in $\{a, b, e, j\}$. The following $N - Y = 444$ voters were not indifferent between all the alternatives in $\{a, b, e, j\}$:

number of voters	b	e	j
$w_1^1 + w_1^{10} + w_1^{19} = 42$	1	1	1
$w_1^2 + w_1^{11} = 9$	1	1	2
$w_1^3 + w_1^{21} = 5$	1	1	3
$w_1^4 + w_1^{13} = 18$	1	2	1
$w_1^5 + w_1^{14} = 11$	1	2	2
$w_1^7 + w_1^{25} = 16$	1	3	1
$w_1^9 + w_1^{27} = 20$	1	3	3
$w_1^{28} + w_1^{37} = 19$	2	1	1
$w_1^{29} + w_1^{38} = 13$	2	1	2
$w_1^{31} + w_1^{40} = 25$	2	2	1
$w_1^{55} + w_1^{73} = 24$	3	1	1
$w_1^{57} + w_1^{75} = 17$	3	1	3
$w_1^{61} + w_1^{79} = 94$	3	3	1
$w_1^{63} + w_1^{81} = 131$	3	3	3
$N - Y = 444$			

Therefore, the $w_3^{32} = 3.087248$ voters with voting pattern #32 are replaced by the following voters:

voting pattern	number of voters	b	c	e	j
#1	$(w_1^1 + w_1^{10} + w_1^{19}) \cdot w_3^{32} / (N - Y) = 0.292037$	1	1	1	1
#2	$(w_1^2 + w_1^{11}) \cdot w_3^{32} / (N - Y) = 0.062579$	1	1	1	2
#3	$(w_1^3 + w_1^{21}) \cdot w_3^{32} / (N - Y) = 0.034766$	1	1	1	3
#4	$(w_1^4 + w_1^{13}) \cdot w_3^{32} / (N - Y) = 0.125159$	1	1	2	1
#5	$(w_1^5 + w_1^{14}) \cdot w_3^{32} / (N - Y) = 0.076486$	1	1	2	2
#7	$(w_1^7 + w_1^{25}) \cdot w_3^{32} / (N - Y) = 0.111252$	1	1	3	1
#9	$(w_1^9 + w_1^{27}) \cdot w_3^{32} / (N - Y) = 0.139065$	1	1	3	3
#28	$(w_1^{28} + w_1^{37}) \cdot w_3^{32} / (N - Y) = 0.132112$	2	1	1	1
#29	$(w_1^{29} + w_1^{38}) \cdot w_3^{32} / (N - Y) = 0.090392$	2	1	1	2
#31	$(w_1^{31} + w_1^{40}) \cdot w_3^{32} / (N - Y) = 0.173832$	2	1	2	1
#55	$(w_1^{55} + w_1^{73}) \cdot w_3^{32} / (N - Y) = 0.166878$	3	1	1	1
#57	$(w_1^{57} + w_1^{75}) \cdot w_3^{32} / (N - Y) = 0.118205$	3	1	1	3
#61	$(w_1^{61} + w_1^{79}) \cdot w_3^{32} / (N - Y) = 0.653607$	3	1	3	1
#63	$(w_1^{63} + w_1^{81}) \cdot w_3^{32} / (N - Y) = 0.910877$	3	1	3	3
	$w_3^{32} = 3.087248$				

Therefore, we get:

voting pattern	number of voters	b	c	e	j
#1	$w_4^1 = w_3^1 + 0.292037 = 18.375828$	1	1	1	1
#2	$w_4^2 = w_3^2 + 0.062579 = 2.251719$	1	1	1	2
#3	$w_4^3 = w_3^3 + 0.034766 = 3.220245$	1	1	1	3
#4	$w_4^4 = w_3^4 + 0.125159 = 4.339720$	1	1	2	1
#5	$w_4^5 = w_3^5 + 0.076486 = 4.307419$	1	1	2	2
#7	$w_4^7 = w_3^7 + 0.111252 = 6.547697$	1	1	3	1
#9	$w_4^9 = w_3^9 + 0.139065 = 3.357288$	1	1	3	3
#10	$w_4^{10} = w_3^{10} = 7.498271$	1	2	1	1
#11	$w_4^{11} = w_3^{11} = 7.432784$	1	2	1	2
#13	$w_4^{13} = w_3^{13} = 15.012914$	1	2	2	1
#19	$w_4^{19} = w_3^{19} = 19.031015$	1	3	1	1
#21	$w_4^{21} = w_3^{21} = 2.320114$	1	3	1	3
#25	$w_4^{25} = w_3^{25} = 11.829774$	1	3	3	1
#27	$w_4^{27} = w_3^{27} = 19.835570$	1	3	3	3
#28	$w_4^{28} = w_3^{28} + 0.132112 = 8.364774$	2	1	1	1
#29	$w_4^{29} = w_3^{29} + 0.090392 = 6.264889$	2	1	1	2
#31	$w_4^{31} = w_3^{31} + 0.173832 = 2.231997$	2	1	2	1
#37	$w_4^{37} = w_3^{37} = 11.319911$	2	2	1	1
#38	$w_4^{38} = w_3^{38} = 7.203579$	2	2	1	2
#40	$w_4^{40} = w_3^{40} = 23.668904$	2	2	2	1
#55	$w_4^{55} = w_3^{55} + 0.166878 = 11.486789$	3	1	1	1
#57	$w_4^{57} = w_3^{57} + 0.118205 = 3.205454$	3	1	1	3
#61	$w_4^{61} = w_3^{61} + 0.653607 = 10.944434$	3	1	3	1
#63	$w_4^{63} = w_3^{63} + 0.910877 = 6.056291$	3	1	3	3
#73	$w_4^{73} = w_3^{73} = 13.378076$	3	3	1	1
#75	$w_4^{75} = w_3^{75} = 14.407159$	3	3	1	3
#79	$w_4^{79} = w_3^{79} = 86.442953$	3	3	3	1
#81	$w_4^{81} = w_3^{81} = 129.664430$	3	3	3	3
	460.000000				

Step 5

We now apply proportional completion to voting pattern #38. In voting pattern #38, the voters are indifferent between the alternatives in $\{a, b, c, j\}$. At stage 1, $Y : = w_1^{38} + w_1^{41} = 20$ voters were indifferent between all the alternatives in $\{a, b, c, j\}$. The following $N - Y = 440$ voters were not indifferent between all the alternatives in $\{a, b, c, j\}$:

number of voters	b	c	j
$w_1^1 + w_1^4 + w_1^7 = 27$	1	1	1
$w_1^2 + w_1^5 = 6$	1	1	2
$w_1^3 + w_1^9 = 6$	1	1	3
$w_1^{10} + w_1^{13} = 21$	1	2	1
$w_1^{11} + w_1^{14} = 14$	1	2	2
$w_1^{19} + w_1^{25} = 28$	1	3	1
$w_1^{21} + w_1^{27} = 19$	1	3	3
$w_1^{28} + w_1^{31} = 10$	2	1	1
$w_1^{29} + w_1^{32} = 9$	2	1	2
$w_1^{37} + w_1^{40} = 34$	2	2	1
$w_1^{55} + w_1^{61} = 21$	3	1	1
$w_1^{57} + w_1^{63} = 8$	3	1	3
$w_1^{73} + w_1^{79} = 97$	3	3	1
$w_1^{75} + w_1^{81} = 140$	3	3	3
$N - Y = 440$			

Therefore, the $w_4^{38} = 7.203579$ voters with voting pattern #38 are replaced by the following voters:

voting pattern	number of voters	b	c	e	j
#1	$(w_1^1 + w_1^4 + w_1^7) \cdot w_4^{38} / (N - Y) = 0.442038$	1	1	1	1
#2	$(w_1^2 + w_1^5) \cdot w_4^{38} / (N - Y) = 0.098231$	1	1	1	2
#3	$(w_1^3 + w_1^9) \cdot w_4^{38} / (N - Y) = 0.098231$	1	1	1	3
#10	$(w_1^{10} + w_1^{13}) \cdot w_4^{38} / (N - Y) = 0.343807$	1	2	1	1
#11	$(w_1^{11} + w_1^{14}) \cdot w_4^{38} / (N - Y) = 0.229205$	1	2	1	2
#19	$(w_1^{19} + w_1^{25}) \cdot w_4^{38} / (N - Y) = 0.458410$	1	3	1	1
#21	$(w_1^{21} + w_1^{27}) \cdot w_4^{38} / (N - Y) = 0.311064$	1	3	1	3
#28	$(w_1^{28} + w_1^{31}) \cdot w_4^{38} / (N - Y) = 0.163718$	2	1	1	1
#29	$(w_1^{29} + w_1^{32}) \cdot w_4^{38} / (N - Y) = 0.147346$	2	1	1	2
#37	$(w_1^{37} + w_1^{40}) \cdot w_4^{38} / (N - Y) = 0.556640$	2	2	1	1
#55	$(w_1^{55} + w_1^{61}) \cdot w_4^{38} / (N - Y) = 0.343807$	3	1	1	1
#57	$(w_1^{57} + w_1^{63}) \cdot w_4^{38} / (N - Y) = 0.130974$	3	1	1	3
#73	$(w_1^{73} + w_1^{79}) \cdot w_4^{38} / (N - Y) = 1.588062$	3	3	1	1
#75	$(w_1^{75} + w_1^{81}) \cdot w_4^{38} / (N - Y) = 2.292048$	3	3	1	3
	$w_4^{38} = 7.203579$				

Therefore, we get:

voting pattern	number of voters	b	c	e	j
#1	$w_5^1 = w_4^1 + 0.442038 = 18.817866$	1	1	1	1
#2	$w_5^2 = w_4^2 + 0.098231 = 2.349950$	1	1	1	2
#3	$w_5^3 = w_4^3 + 0.098231 = 3.318476$	1	1	1	3
#4	$w_5^4 = w_4^4 = 4.339720$	1	1	2	1
#5	$w_5^5 = w_4^5 = 4.307419$	1	1	2	2
#7	$w_5^7 = w_4^7 = 6.547697$	1	1	3	1
#9	$w_5^9 = w_4^9 = 3.357288$	1	1	3	3
#10	$w_5^{10} = w_4^{10} + 0.343807 = 7.842079$	1	2	1	1
#11	$w_5^{11} = w_4^{11} + 0.229205 = 7.661989$	1	2	1	2
#13	$w_5^{13} = w_4^{13} = 15.012914$	1	2	2	1
#19	$w_5^{19} = w_4^{19} + 0.458410 = 19.489424$	1	3	1	1
#21	$w_5^{21} = w_4^{21} + 0.311064 = 2.631178$	1	3	1	3
#25	$w_5^{25} = w_4^{25} = 11.829774$	1	3	3	1
#27	$w_5^{27} = w_4^{27} = 19.835570$	1	3	3	3
#28	$w_5^{28} = w_4^{28} + 0.163718 = 8.528492$	2	1	1	1
#29	$w_5^{29} = w_4^{29} + 0.147346 = 6.412235$	2	1	1	2
#31	$w_5^{31} = w_4^{31} = 2.231997$	2	1	2	1
#37	$w_5^{37} = w_4^{37} + 0.556640 = 11.876551$	2	2	1	1
#40	$w_5^{40} = w_4^{40} = 23.668904$	2	2	2	1
#55	$w_5^{55} = w_4^{55} + 0.343807 = 11.830596$	3	1	1	1
#57	$w_5^{57} = w_4^{57} + 0.130974 = 3.336428$	3	1	1	3
#61	$w_5^{61} = w_4^{61} = 10.944434$	3	1	3	1
#63	$w_5^{63} = w_4^{63} = 6.056291$	3	1	3	3
#73	$w_5^{73} = w_4^{73} + 1.588062 = 14.966138$	3	3	1	1
#75	$w_5^{75} = w_4^{75} + 2.292048 = 16.699207$	3	3	1	3
#79	$w_5^{79} = w_4^{79} = 86.442953$	3	3	3	1
#81	$w_5^{81} = w_4^{81} = 129.664430$	3	3	3	3
	460.000000				

Step 6

We now apply proportional completion to voting pattern #40. In voting pattern #40, the voters are indifferent between the alternatives in $\{a, b, c, e\}$. At stage 1, $Y := w_1^{40} + w_1^{41} = 36$ voters were indifferent between all the alternatives in $\{a, b, c, e\}$. The following $N - Y = 424$ voters were not indifferent between all the alternatives in $\{a, b, c, e\}$:

number of voters	b	c	e
$w_1^1 + w_1^2 + w_1^3 = 22$	1	1	1
$w_1^4 + w_1^5 = 8$	1	1	2
$w_1^7 + w_1^9 = 9$	1	1	3
$w_1^{10} + w_1^{11} = 14$	1	2	1
$w_1^{13} + w_1^{14} = 21$	1	2	2
$w_1^{19} + w_1^{21} = 20$	1	3	1
$w_1^{25} + w_1^{27} = 27$	1	3	3
$w_1^{28} + w_1^{29} = 14$	2	1	1
$w_1^{31} + w_1^{32} = 5$	2	1	2
$w_1^{37} + w_1^{38} = 18$	2	2	1
$w_1^{55} + w_1^{57} = 14$	3	1	1
$w_1^{61} + w_1^{63} = 15$	3	1	3
$w_1^{73} + w_1^{75} = 27$	3	3	1
$w_1^{79} + w_1^{81} = 210$	3	3	3
$N - Y = 424$			

Therefore, the $w_5^{40} = 23.668904$ voters with voting pattern #40 are replaced by the following voters:

voting pattern	number of voters	b	c	e	j
#1	$(w_1^1 + w_1^2 + w_1^3) \cdot w_5^{40} / (N - Y) = 1.228103$	1	1	1	1
#4	$(w_1^4 + w_1^5) \cdot w_5^{40} / (N - Y) = 0.446583$	1	1	2	1
#7	$(w_1^7 + w_1^9) \cdot w_5^{40} / (N - Y) = 0.502406$	1	1	3	1
#10	$(w_1^{10} + w_1^{11}) \cdot w_5^{40} / (N - Y) = 0.781520$	1	2	1	1
#13	$(w_1^{13} + w_1^{14}) \cdot w_5^{40} / (N - Y) = 1.172281$	1	2	2	1
#19	$(w_1^{19} + w_1^{21}) \cdot w_5^{40} / (N - Y) = 1.116458$	1	3	1	1
#25	$(w_1^{25} + w_1^{27}) \cdot w_5^{40} / (N - Y) = 1.507218$	1	3	3	1
#28	$(w_1^{28} + w_1^{29}) \cdot w_5^{40} / (N - Y) = 0.781520$	2	1	1	1
#31	$(w_1^{31} + w_1^{32}) \cdot w_5^{40} / (N - Y) = 0.279114$	2	1	2	1
#37	$(w_1^{37} + w_1^{38}) \cdot w_5^{40} / (N - Y) = 1.004812$	2	2	1	1
#55	$(w_1^{55} + w_1^{57}) \cdot w_5^{40} / (N - Y) = 0.781520$	3	1	1	1
#61	$(w_1^{61} + w_1^{63}) \cdot w_5^{40} / (N - Y) = 0.837343$	3	1	3	1
#73	$(w_1^{73} + w_1^{75}) \cdot w_5^{40} / (N - Y) = 1.507218$	3	3	1	1
#79	$(w_1^{79} + w_1^{81}) \cdot w_5^{40} / (N - Y) = 11.722806$	3	3	3	1
	$w_5^{40} = 23.668904$				

Therefore, we get:

voting pattern	number of voters	b	c	e	j
#1	$w_6^1 = w_5^1 + 1.228103 = 20.045969$	1	1	1	1
#2	$w_6^2 = w_5^2 = 2.349950$	1	1	1	2
#3	$w_6^3 = w_5^3 = 3.318476$	1	1	1	3
#4	$w_6^4 = w_5^4 + 0.446583 = 4.786304$	1	1	2	1
#5	$w_6^5 = w_5^5 = 4.307419$	1	1	2	2
#7	$w_6^7 = w_5^7 + 0.502406 = 7.050103$	1	1	3	1
#9	$w_6^9 = w_5^9 = 3.357288$	1	1	3	3
#10	$w_6^{10} = w_5^{10} + 0.781520 = 8.623599$	1	2	1	1
#11	$w_6^{11} = w_5^{11} = 7.661989$	1	2	1	2
#13	$w_6^{13} = w_5^{13} + 1.172281 = 16.185195$	1	2	2	1
#19	$w_6^{19} = w_5^{19} + 1.116458 = 20.605882$	1	3	1	1
#21	$w_6^{21} = w_5^{21} = 2.631178$	1	3	1	3
#25	$w_6^{25} = w_5^{25} + 1.507218 = 13.336992$	1	3	3	1
#27	$w_6^{27} = w_5^{27} = 19.835570$	1	3	3	3
#28	$w_6^{28} = w_5^{28} + 0.781520 = 9.310012$	2	1	1	1
#29	$w_6^{29} = w_5^{29} = 6.412235$	2	1	1	2
#31	$w_6^{31} = w_5^{31} + 0.279114 = 2.511112$	2	1	2	1
#37	$w_6^{37} = w_5^{37} + 1.004812 = 12.881363$	2	2	1	1
#55	$w_6^{55} = w_5^{55} + 0.781520 = 12.612116$	3	1	1	1
#57	$w_6^{57} = w_5^{57} = 3.336428$	3	1	1	3
#61	$w_6^{61} = w_5^{61} + 0.837343 = 11.781778$	3	1	3	1
#63	$w_6^{63} = w_5^{63} = 6.056291$	3	1	3	3
#73	$w_6^{73} = w_5^{73} + 1.507218 = 16.473356$	3	3	1	1
#75	$w_6^{75} = w_5^{75} = 16.699207$	3	3	1	3
#79	$w_6^{79} = w_5^{79} + 11.722806 = 98.165759$	3	3	3	1
#81	$w_6^{81} = w_5^{81} = 129.664430$	3	3	3	3
	460.000000				

Step 7

We now apply proportional completion to voting pattern #5. In voting pattern #5, the voters are indifferent between the alternatives in $\{a, e, j\}$. At stage 1, $Y := w_1^5 + w_1^{14} + w_1^{32} + w_1^{41} = 27$ voters were indifferent between all the alternatives in $\{a, e, j\}$. The following $N - Y = 433$ voters were not indifferent between all the alternatives in $\{a, e, j\}$:

number of voters	e	j
$w_1^1 + w_1^{10} + w_1^{19} + w_1^{28} + w_1^{37} + w_1^{55} + w_1^{73} = 85$	1	1
$w_1^2 + w_1^{11} + w_1^{29} + w_1^{38} = 22$	1	2
$w_1^3 + w_1^{21} + w_1^{57} + w_1^{75} = 22$	1	3
$w_1^4 + w_1^{13} + w_1^{31} + w_1^{40} = 43$	2	1
$w_1^7 + w_1^{25} + w_1^{61} + w_1^{79} = 110$	3	1
$w_1^9 + w_1^{27} + w_1^{63} + w_1^{81} = 151$	3	3
$N - Y = 433$		

Therefore, the $w_6^5 = 4.307419$ voters with voting pattern #5 are replaced by the following voters:

voting pattern	number of voters	b	c	e	j
#1	$(w_1^1 + w_1^{10} + w_1^{19} + w_1^{28} + w_1^{37} + w_1^{55} + w_1^{73}) \cdot w_6^5 / (N - Y) = 0.845567$	1	1	1	1
#2	$(w_1^2 + w_1^{11} + w_1^{29} + w_1^{38}) \cdot w_6^5 / (N - Y) = 0.218853$	1	1	1	2
#3	$(w_1^3 + w_1^{21} + w_1^{57} + w_1^{75}) \cdot w_6^5 / (N - Y) = 0.218853$	1	1	1	3
#4	$(w_1^4 + w_1^{13} + w_1^{31} + w_1^{40}) \cdot w_6^5 / (N - Y) = 0.427758$	1	1	2	1
#7	$(w_1^7 + w_1^{25} + w_1^{61} + w_1^{79}) \cdot w_6^5 / (N - Y) = 1.094264$	1	1	3	1
#9	$(w_1^9 + w_1^{27} + w_1^{63} + w_1^{81}) \cdot w_6^5 / (N - Y) = 1.502125$	1	1	3	3
	$w_6^5 = 4.307419$				

Therefore, we get:

voting pattern	number of voters	b	c	e	j
#1	$w_7^1 = w_6^1 + 0.845567 = 20.891537$	1	1	1	1
#2	$w_7^2 = w_6^2 + 0.218853 = 2.568802$	1	1	1	2
#3	$w_7^3 = w_6^3 + 0.218853 = 3.537329$	1	1	1	3
#4	$w_7^4 = w_6^4 + 0.427758 = 5.214061$	1	1	2	1
#7	$w_7^7 = w_6^7 + 1.094264 = 8.144367$	1	1	3	1
#9	$w_7^9 = w_6^9 + 1.502125 = 4.859413$	1	1	3	3
#10	$w_7^{10} = w_6^{10} = 8.623599$	1	2	1	1
#11	$w_7^{11} = w_6^{11} = 7.661989$	1	2	1	2
#13	$w_7^{13} = w_6^{13} = 16.185195$	1	2	2	1
#19	$w_7^{19} = w_6^{19} = 20.605882$	1	3	1	1
#21	$w_7^{21} = w_6^{21} = 2.631178$	1	3	1	3
#25	$w_7^{25} = w_6^{25} = 13.336992$	1	3	3	1
#27	$w_7^{27} = w_6^{27} = 19.835570$	1	3	3	3
#28	$w_7^{28} = w_6^{28} = 9.310012$	2	1	1	1
#29	$w_7^{29} = w_6^{29} = 6.412235$	2	1	1	2
#31	$w_7^{31} = w_6^{31} = 2.511112$	2	1	2	1
#37	$w_7^{37} = w_6^{37} = 12.881363$	2	2	1	1
#55	$w_7^{55} = w_6^{55} = 12.612116$	3	1	1	1
#57	$w_7^{57} = w_6^{57} = 3.336428$	3	1	1	3
#61	$w_7^{61} = w_6^{61} = 11.781778$	3	1	3	1
#63	$w_7^{63} = w_6^{63} = 6.056291$	3	1	3	3
#73	$w_7^{73} = w_6^{73} = 16.473356$	3	3	1	1
#75	$w_7^{75} = w_6^{75} = 16.699207$	3	3	1	3
#79	$w_7^{79} = w_6^{79} = 98.165759$	3	3	3	1
#81	$w_7^{81} = w_6^{81} = 129.664430$	3	3	3	3
	460.000000				

Step 8

We now apply proportional completion to voting pattern #11. In voting pattern #11, the voters are indifferent between the alternatives in $\{a, c, j\}$. At stage 1, $Y := w_1^{11} + w_1^{14} + w_1^{38} + w_1^{41} = 34$ voters were indifferent between all the alternatives in $\{a, c, j\}$. The following $N - Y = 426$ voters were not indifferent between all the alternatives in $\{a, c, j\}$:

number of voters	c	j
$w_1^1 + w_1^4 + w_1^7 + w_1^{28} + w_1^{31} + w_1^{55} + w_1^{61} = 58$	1	1
$w_1^2 + w_1^5 + w_1^{29} + w_1^{32} = 15$	1	2
$w_1^3 + w_1^9 + w_1^{57} + w_1^{63} = 14$	1	3
$w_1^{10} + w_1^{13} + w_1^{37} + w_1^{40} = 55$	2	1
$w_1^{19} + w_1^{25} + w_1^{73} + w_1^{79} = 125$	3	1
$w_1^{21} + w_1^{27} + w_1^{75} + w_1^{81} = 159$	3	3
$N - Y = 426$		

Therefore, the $w_7^{11} = 7.661989$ voters with voting pattern #11 are replaced by the following voters:

voting pattern	number of voters	b	c	e	j
#1	$(w_1^1 + w_1^4 + w_1^7 + w_1^{28} + w_1^{31} + w_1^{55} + w_1^{61}) \cdot w_7^{11} / (N - Y) = 1.043182$	1	1	1	1
#2	$(w_1^2 + w_1^5 + w_1^{29} + w_1^{32}) \cdot w_7^{11} / (N - Y) = 0.269788$	1	1	1	2
#3	$(w_1^3 + w_1^9 + w_1^{57} + w_1^{63}) \cdot w_7^{11} / (N - Y) = 0.251802$	1	1	1	3
#10	$(w_1^{10} + w_1^{13} + w_1^{37} + w_1^{40}) \cdot w_7^{11} / (N - Y) = 0.989224$	1	2	1	1
#19	$(w_1^{19} + w_1^{25} + w_1^{73} + w_1^{79}) \cdot w_7^{11} / (N - Y) = 2.248236$	1	3	1	1
#21	$(w_1^{21} + w_1^{27} + w_1^{75} + w_1^{81}) \cdot w_7^{11} / (N - Y) = 2.859756$	1	3	1	3
	$w_7^{11} = 7.661989$				

Therefore, we get:

voting pattern	number of voters	b	c	e	j
#1	$w_8^1 = w_7^1 + 1.043182 = 21.934718$	1	1	1	1
#2	$w_8^2 = w_7^2 + 0.269788 = 2.838591$	1	1	1	2
#3	$w_8^3 = w_7^3 + 0.251802 = 3.789131$	1	1	1	3
#4	$w_8^4 = w_7^4 = 5.214061$	1	1	2	1
#7	$w_8^7 = w_7^7 = 8.144367$	1	1	3	1
#9	$w_8^9 = w_7^9 = 4.859413$	1	1	3	3
#10	$w_8^{10} = w_7^{10} + 0.989224 = 9.612823$	1	2	1	1
#13	$w_8^{13} = w_7^{13} = 16.185199$	1	2	2	1
#19	$w_8^{19} = w_7^{19} + 2.248236 = 22.854118$	1	3	1	1
#21	$w_8^{21} = w_7^{21} + 2.859756 = 5.490934$	1	3	1	3
#25	$w_8^{25} = w_7^{25} = 13.336992$	1	3	3	1
#27	$w_8^{27} = w_7^{27} = 19.835570$	1	3	3	3
#28	$w_8^{28} = w_7^{28} = 9.310012$	2	1	1	1
#29	$w_8^{29} = w_7^{29} = 6.412235$	2	1	1	2
#31	$w_8^{31} = w_7^{31} = 2.511112$	2	1	2	1
#37	$w_8^{37} = w_7^{37} = 12.881363$	2	2	1	1
#55	$w_8^{55} = w_7^{55} = 12.612116$	3	1	1	1
#57	$w_8^{57} = w_7^{57} = 3.336428$	3	1	1	3
#61	$w_8^{61} = w_7^{61} = 11.781778$	3	1	3	1
#63	$w_8^{63} = w_7^{63} = 6.056291$	3	1	3	3
#73	$w_8^{73} = w_7^{73} = 16.473356$	3	3	1	1
#75	$w_8^{75} = w_7^{75} = 16.699207$	3	3	1	3
#79	$w_8^{79} = w_7^{79} = 98.165759$	3	3	3	1
#81	$w_8^{81} = w_7^{81} = 129.664430$	3	3	3	3
	460.000000				

Step 9

We now apply proportional completion to voting pattern #13. In voting pattern #13, the voters are indifferent between the alternatives in $\{a, c, e\}$. At stage 1, $Y := w_1^{13} + w_1^{14} + w_1^{40} + w_1^{41} = 57$ voters were indifferent between all the alternatives in $\{a, c, e\}$. The following $N - Y = 403$ voters were not indifferent between all the alternatives in $\{a, c, e\}$:

number of voters	c	e
$w_1^1 + w_1^2 + w_1^3 + w_1^{28} + w_1^{29} + w_1^{55} + w_1^{57} = 50$	1	1
$w_1^4 + w_1^5 + w_1^{31} + w_1^{32} = 13$	1	2
$w_1^7 + w_1^9 + w_1^{61} + w_1^{63} = 24$	1	3
$w_1^{10} + w_1^{11} + w_1^{37} + w_1^{38} = 32$	2	1
$w_1^{19} + w_1^{21} + w_1^{73} + w_1^{75} = 47$	3	1
$w_1^{25} + w_1^{27} + w_1^{79} + w_1^{81} = 237$	3	3
$N - Y = 403$		

Therefore, the $w_8^{13} = 16.185195$ voters with voting pattern #13 are replaced by the following voters:

voting pattern	number of voters	b	c	e	j
#1	$(w_1^1 + w_1^2 + w_1^3 + w_1^{28} + w_1^{29} + w_1^{55} + w_1^{57}) \cdot w_8^{13} / (N - Y) = 2.008089$	1	1	1	1
#4	$(w_1^4 + w_1^5 + w_1^{31} + w_1^{32}) \cdot w_8^{13} / (N - Y) = 0.522103$	1	1	2	1
#7	$(w_1^7 + w_1^9 + w_1^{61} + w_1^{63}) \cdot w_8^{13} / (N - Y) = 0.963883$	1	1	3	1
#10	$(w_1^{10} + w_1^{11} + w_1^{37} + w_1^{38}) \cdot w_8^{13} / (N - Y) = 1.285177$	1	2	1	1
#19	$(w_1^{19} + w_1^{21} + w_1^{73} + w_1^{75}) \cdot w_8^{13} / (N - Y) = 1.887603$	1	3	1	1
#25	$(w_1^{25} + w_1^{27} + w_1^{79} + w_1^{81}) \cdot w_8^{13} / (N - Y) = 9.518340$	1	3	3	1
	$w_8^{13} = 16.185195$				

Therefore, we get:

voting pattern	number of voters	b	c	e	j
#1	$w_9^1 = w_8^1 + 2.008089 = 23.942807$	1	1	1	1
#2	$w_9^2 = w_8^2 = 2.838591$	1	1	1	2
#3	$w_9^3 = w_8^3 = 3.789131$	1	1	1	3
#4	$w_9^4 = w_8^4 + 0.522103 = 5.736164$	1	1	2	1
#7	$w_9^7 = w_8^7 + 0.963883 = 9.108249$	1	1	3	1
#9	$w_9^9 = w_8^9 = 4.859413$	1	1	3	3
#10	$w_9^{10} = w_8^{10} + 1.285177 = 10.898000$	1	2	1	1
#19	$w_9^{19} = w_8^{19} + 1.887603 = 24.741722$	1	3	1	1
#21	$w_9^{21} = w_8^{21} = 5.490934$	1	3	1	3
#25	$w_9^{25} = w_8^{25} + 9.518340 = 22.855333$	1	3	3	1
#27	$w_9^{27} = w_8^{27} = 19.835570$	1	3	3	3
#28	$w_9^{28} = w_8^{28} = 9.310012$	2	1	1	1
#29	$w_9^{29} = w_8^{29} = 6.412235$	2	1	1	2
#31	$w_9^{31} = w_8^{31} = 2.511112$	2	1	2	1
#37	$w_9^{37} = w_8^{37} = 12.881363$	2	2	1	1
#55	$w_9^{55} = w_8^{55} = 12.612116$	3	1	1	1
#57	$w_9^{57} = w_8^{57} = 3.336428$	3	1	1	3
#61	$w_9^{61} = w_8^{61} = 11.781778$	3	1	3	1
#63	$w_9^{63} = w_8^{63} = 6.056291$	3	1	3	3
#73	$w_9^{73} = w_8^{73} = 16.473356$	3	3	1	1
#75	$w_9^{75} = w_8^{75} = 16.699207$	3	3	1	3
#79	$w_9^{79} = w_8^{79} = 98.165759$	3	3	3	1
#81	$w_9^{81} = w_8^{81} = 129.664430$	3	3	3	3
	460.000000				

Step 10

We now apply proportional completion to voting pattern #29. In voting pattern #29, the voters are indifferent between the alternatives in $\{a, b, j\}$. At stage 1, $Y := w_1^{29} + w_1^{32} + w_1^{38} = 29$ voters were indifferent between all the alternatives in $\{a, b, j\}$. The following $N - Y = 431$ voters were not indifferent between all the alternatives in $\{a, b, j\}$:

number of voters	b	j
$w_1^1 + w_1^4 + w_1^7 + w_1^{10} + w_1^{13} + w_1^{19} + w_1^{25} = 76$	1	1
$w_1^2 + w_1^5 + w_1^{11} + w_1^{14} = 20$	1	2
$w_1^3 + w_1^9 + w_1^{21} + w_1^{27} = 25$	1	3
$w_1^{28} + w_1^{31} + w_1^{37} + w_1^{40} = 44$	2	1
$w_1^{55} + w_1^{61} + w_1^{73} + w_1^{79} = 118$	3	1
$w_1^{57} + w_1^{63} + w_1^{75} + w_1^{81} = 148$	3	3
$N - Y = 431$		

Therefore, the $w_9^{29} = 6.412235$ voters with voting pattern #29 are replaced by the following voters:

voting pattern	number of voters	b	c	e	j
#1	$(w_1^1 + w_1^4 + w_1^7 + w_1^{10} + w_1^{13} + w_1^{19} + w_1^{25}) \cdot w_9^{29} / (N - Y) = 1.130696$	1	1	1	1
#2	$(w_1^2 + w_1^5 + w_1^{11} + w_1^{14}) \cdot w_9^{29} / (N - Y) = 0.297552$	1	1	1	2
#3	$(w_1^3 + w_1^9 + w_1^{21} + w_1^{27}) \cdot w_9^{29} / (N - Y) = 0.371939$	1	1	1	3
#28	$(w_1^{28} + w_1^{31} + w_1^{37} + w_1^{40}) \cdot w_9^{29} / (N - Y) = 0.654613$	2	1	1	1
#55	$(w_1^{55} + w_1^{61} + w_1^{73} + w_1^{79}) \cdot w_9^{29} / (N - Y) = 1.755554$	3	1	1	1
#57	$(w_1^{57} + w_1^{63} + w_1^{75} + w_1^{81}) \cdot w_9^{29} / (N - Y) = 2.201881$	3	1	1	3
	$w_9^{29} = 6.412235$				

Therefore, we get:

voting pattern	number of voters	b	c	e	j
#1	$w_{10}^1 = w_9^1 + 1.130696 = 25.073503$	1	1	1	1
#2	$w_{10}^2 = w_9^2 + 0.297552 = 3.136142$	1	1	1	2
#3	$w_{10}^3 = w_9^3 + 0.371939 = 4.161070$	1	1	1	3
#4	$w_{10}^4 = w_9^4 = 5.736164$	1	1	2	1
#7	$w_{10}^7 = w_9^7 = 9.108249$	1	1	3	1
#9	$w_{10}^9 = w_9^9 = 4.859413$	1	1	3	3
#10	$w_{10}^{10} = w_9^{10} = 10.898000$	1	2	1	1
#19	$w_{10}^{19} = w_9^{19} = 24.741722$	1	3	1	1
#21	$w_{10}^{21} = w_9^{21} = 5.490934$	1	3	1	3
#25	$w_{10}^{25} = w_9^{25} = 22.855333$	1	3	3	1
#27	$w_{10}^{27} = w_9^{27} = 19.835570$	1	3	3	3
#28	$w_{10}^{28} = w_9^{28} + 0.654613 = 9.964626$	2	1	1	1
#31	$w_{10}^{31} = w_9^{31} = 2.511112$	2	1	2	1
#37	$w_{10}^{37} = w_9^{37} = 12.881363$	2	2	1	1
#55	$w_{10}^{55} = w_9^{55} + 1.755554 = 14.367670$	3	1	1	1
#57	$w_{10}^{57} = w_9^{57} + 2.201881 = 5.538309$	3	1	1	3
#61	$w_{10}^{61} = w_9^{61} = 11.781778$	3	1	3	1
#63	$w_{10}^{63} = w_9^{63} = 6.056291$	3	1	3	3
#73	$w_{10}^{73} = w_9^{73} = 16.473356$	3	3	1	1
#75	$w_{10}^{75} = w_9^{75} = 16.699207$	3	3	1	3
#79	$w_{10}^{79} = w_9^{79} = 98.165759$	3	3	3	1
#81	$w_{10}^{81} = w_9^{81} = 129.664430$	3	3	3	3
	460.000000				

Step 11

We now apply proportional completion to voting pattern #31. In voting pattern #31, the voters are indifferent between the alternatives in $\{a, b, e\}$. At stage 1, $Y := w_1^{31} + w_1^{32} + w_1^{40} + w_1^{41} = 41$ voters were indifferent between all the alternatives in $\{a, b, e\}$. The following $N - Y = 419$ voters were not indifferent between all the alternatives in $\{a, b, e\}$:

number of voters	b	e
$w_1^1 + w_1^2 + w_1^3 + w_1^{10} + w_1^{11} + w_1^{19} + w_1^{21} = 56$	1	1
$w_1^4 + w_1^5 + w_1^{13} + w_1^{14} = 29$	1	2
$w_1^7 + w_1^9 + w_1^{25} + w_1^{27} = 36$	1	3
$w_1^{28} + w_1^{29} + w_1^{37} + w_1^{38} = 32$	2	1
$w_1^{55} + w_1^{57} + w_1^{73} + w_1^{75} = 41$	3	1
$w_1^{61} + w_1^{63} + w_1^{79} + w_1^{81} = 225$	3	3
$N - Y = 419$		

Therefore, the $w_{10}^{31} = 2.511112$ voters with voting pattern #31 are replaced by the following voters:

voting pattern	number of voters	b	c	e	j
#1	$(w_1^1 + w_1^2 + w_1^3 + w_1^{10} + w_1^{11} + w_1^{19} + w_1^{21}) \cdot w_{10}^{31} / (N - Y) = 0.335614$	1	1	1	1
#4	$(w_1^4 + w_1^5 + w_1^{13} + w_1^{14}) \cdot w_{10}^{31} / (N - Y) = 0.173800$	1	1	2	1
#7	$(w_1^7 + w_1^9 + w_1^{25} + w_1^{27}) \cdot w_{10}^{31} / (N - Y) = 0.215752$	1	1	3	1
#28	$(w_1^{28} + w_1^{29} + w_1^{37} + w_1^{38}) \cdot w_{10}^{31} / (N - Y) = 0.191779$	2	1	1	1
#55	$(w_1^{55} + w_1^{57} + w_1^{73} + w_1^{75}) \cdot w_{10}^{31} / (N - Y) = 0.245717$	3	1	1	1
#61	$(w_1^{61} + w_1^{63} + w_1^{79} + w_1^{81}) \cdot w_{10}^{31} / (N - Y) = 1.348449$	3	1	3	1
	$w_{10}^{31} = 2.511112$				

Therefore, we get:

voting pattern	number of voters	b	c	e	j
#1	$w_{11}^1 = w_{10}^1 + 0.335614 = 25.409117$	1	1	1	1
#2	$w_{11}^2 = w_{10}^2 = 3.136142$	1	1	1	2
#3	$w_{11}^3 = w_{10}^3 = 4.161070$	1	1	1	3
#4	$w_{11}^4 = w_{10}^4 + 0.173800 = 5.909964$	1	1	2	1
#7	$w_{11}^7 = w_{10}^7 + 0.215752 = 9.324001$	1	1	3	1
#9	$w_{11}^9 = w_{10}^9 = 4.859413$	1	1	3	3
#10	$w_{11}^{10} = w_{10}^{10} = 10.898000$	1	2	1	1
#19	$w_{11}^{19} = w_{10}^{19} = 24.741722$	1	3	1	1
#21	$w_{11}^{21} = w_{10}^{21} = 5.490934$	1	3	1	3
#25	$w_{11}^{25} = w_{10}^{25} = 22.855333$	1	3	3	1
#27	$w_{11}^{27} = w_{10}^{27} = 19.835570$	1	3	3	3
#28	$w_{11}^{28} = w_{10}^{28} + 0.191779 = 10.156405$	2	1	1	1
#37	$w_{11}^{37} = w_{10}^{37} = 12.881363$	2	2	1	1
#55	$w_{11}^{55} = w_{10}^{55} + 0.245717 = 14.613388$	3	1	1	1
#57	$w_{11}^{57} = w_{10}^{57} = 5.538309$	3	1	1	3
#61	$w_{11}^{61} = w_{10}^{61} + 1.348449 = 13.130227$	3	1	3	1
#63	$w_{11}^{63} = w_{10}^{63} = 6.056291$	3	1	3	3
#73	$w_{11}^{73} = w_{10}^{73} = 16.473356$	3	3	1	1
#75	$w_{11}^{75} = w_{10}^{75} = 16.699207$	3	3	1	3
#79	$w_{11}^{79} = w_{10}^{79} = 98.165759$	3	3	3	1
#81	$w_{11}^{81} = w_{10}^{81} = 129.664430$	3	3	3	3
	460.000000				

Step 12

We now apply proportional completion to voting pattern #37. In voting pattern #37, the voters are indifferent between the alternatives in $\{a, b, c\}$. At stage 1, $Y := w_1^{37} + w_1^{38} + w_1^{40} + w_1^{41} = 54$ voters were indifferent between all the alternatives in $\{a, b, c\}$. The following $N - Y = 406$ voters were not indifferent between all the alternatives in $\{a, b, c\}$:

number of voters	b	c
$w_1^1 + w_1^2 + w_1^3 + w_1^4 + w_1^5 + w_1^7 + w_1^9 = 39$	1	1
$w_1^{10} + w_1^{11} + w_1^{13} + w_1^{14} = 35$	1	2
$w_1^{19} + w_1^{21} + w_1^{25} + w_1^{27} = 47$	1	3
$w_1^{28} + w_1^{29} + w_1^{31} + w_1^{32} = 19$	2	1
$w_1^{55} + w_1^{57} + w_1^{61} + w_1^{63} = 29$	3	1
$w_1^{73} + w_1^{75} + w_1^{79} + w_1^{81} = 237$	3	3
$N - Y = 406$		

Therefore, the $w_{11}^{37} = 12.881363$ voters with voting pattern #37 are replaced by the following voters:

voting pattern	number of voters	b	c	e	j
#1	$(w_1^1 + w_1^2 + w_1^3 + w_1^4 + w_1^5 + w_1^7 + w_1^9) \cdot w_{11}^{37} / (N - Y) = 1.237372$	1	1	1	1
#10	$(w_1^{10} + w_1^{11} + w_1^{13} + w_1^{14}) \cdot w_{11}^{37} / (N - Y) = 1.110462$	1	2	1	1
#19	$(w_1^{19} + w_1^{21} + w_1^{25} + w_1^{27}) \cdot w_{11}^{37} / (N - Y) = 1.491192$	1	3	1	1
#28	$(w_1^{28} + w_1^{29} + w_1^{31} + w_1^{32}) \cdot w_{11}^{37} / (N - Y) = 0.602822$	2	1	1	1
#55	$(w_1^{55} + w_1^{57} + w_1^{61} + w_1^{63}) \cdot w_{11}^{37} / (N - Y) = 0.920097$	3	1	1	1
#73	$(w_1^{73} + w_1^{75} + w_1^{79} + w_1^{81}) \cdot w_{11}^{37} / (N - Y) = 7.519416$	3	3	1	1
	$w_{11}^{37} = 12.881363$				

Therefore, we get:

voting pattern	number of voters	b	c	e	j
#1	$w_{12}^1 = w_{11}^1 + 1.237372 = 26.646489$	1	1	1	1
#2	$w_{12}^2 = w_{11}^2 = 3.136142$	1	1	1	2
#3	$w_{12}^3 = w_{11}^3 = 4.161070$	1	1	1	3
#4	$w_{12}^4 = w_{11}^4 = 5.909964$	1	1	2	1
#7	$w_{12}^7 = w_{11}^7 = 9.324001$	1	1	3	1
#9	$w_{12}^9 = w_{11}^9 = 4.859413$	1	1	3	3
#10	$w_{12}^{10} = w_{11}^{10} + 1.110462 = 12.008462$	1	2	1	1
#19	$w_{12}^{19} = w_{11}^{19} + 1.491192 = 26.232914$	1	3	1	1
#21	$w_{12}^{21} = w_{11}^{21} = 5.490934$	1	3	1	3
#25	$w_{12}^{25} = w_{11}^{25} = 22.855333$	1	3	3	1
#27	$w_{12}^{27} = w_{11}^{27} = 19.835570$	1	3	3	3
#28	$w_{12}^{28} = w_{11}^{28} + 0.602822 = 10.759227$	2	1	1	1
#55	$w_{12}^{55} = w_{11}^{55} + 0.920097 = 15.533485$	3	1	1	1
#57	$w_{12}^{57} = w_{11}^{57} = 5.538309$	3	1	1	3
#61	$w_{12}^{61} = w_{11}^{61} = 13.130227$	3	1	3	1
#63	$w_{12}^{63} = w_{11}^{63} = 6.056291$	3	1	3	3
#73	$w_{12}^{73} = w_{11}^{73} + 7.519416 = 23.992772$	3	3	1	1
#75	$w_{12}^{75} = w_{11}^{75} = 16.699207$	3	3	1	3
#79	$w_{12}^{79} = w_{11}^{79} = 98.165759$	3	3	3	1
#81	$w_{12}^{81} = w_{11}^{81} = 129.664430$	3	3	3	3
	460.000000				

Step 13

We now apply proportional completion to voting pattern #2. In voting pattern #2, the voters are indifferent between the alternatives in $\{a, j\}$. At stage 1, $Y := w_1^2 + w_1^5 + w_1^{11} + w_1^{14} + w_1^{29} + w_1^{32} + w_1^{38} + w_1^{41} = 49$ voters were indifferent between all the alternatives in $\{a, j\}$. The following $N - Y = 411$ voters were not indifferent between all the alternatives in $\{a, j\}$:

number of voters	j
$w_1^1 + w_1^4 + w_1^7 + w_1^{10} + w_1^{13} + w_1^{19} + w_1^{25} + w_1^{28} + w_1^{31} + w_1^{37} + w_1^{40} + w_1^{55} + w_1^{61} + w_1^{73} + w_1^{79} = 238$	1
$w_1^3 + w_1^9 + w_1^{21} + w_1^{27} + w_1^{57} + w_1^{63} + w_1^{75} + w_1^{81} = 173$	3
$N - Y = 411$	

Therefore, the $w_{12}^2 = 3.136142$ voters with voting pattern #2 are replaced by the following voters:

voting pattern	number of voters	b	c	e	j
#1	$(w_1^1 + w_1^4 + w_1^7 + w_1^{10} + w_1^{13} + w_1^{19} + w_1^{25} + w_1^{28} + w_1^{31} + w_1^{37} + w_1^{40} + w_1^{55} + w_1^{61} + w_1^{73} + w_1^{79}) \cdot w_{12}^2 / (N - Y) = 1.816063$	1	1	1	1
#3	$(w_1^3 + w_1^9 + w_1^{21} + w_1^{27} + w_1^{57} + w_1^{63} + w_1^{75} + w_1^{81}) \cdot w_{12}^2 / (N - Y) = 1.320079$	1	1	1	3
	$w_{12}^2 = 3.136142$				

Therefore, we get:

voting pattern	number of voters	b	c	e	j
#1	$w_{13}^1 = w_{12}^1 + 1.816063 = 28.462552$	1	1	1	1
#3	$w_{13}^3 = w_{12}^3 + 1.320079 = 5.481150$	1	1	1	3
#4	$w_{13}^4 = w_{12}^4 = 5.909964$	1	1	2	1
#7	$w_{13}^7 = w_{12}^7 = 9.324001$	1	1	3	1
#9	$w_{13}^9 = w_{12}^9 = 4.859413$	1	1	3	3
#10	$w_{13}^{10} = w_{12}^{10} = 12.008462$	1	2	1	1
#19	$w_{13}^{19} = w_{12}^{19} = 26.232914$	1	3	1	1
#21	$w_{13}^{21} = w_{12}^{21} = 5.490934$	1	3	1	3
#25	$w_{13}^{25} = w_{12}^{25} = 22.855333$	1	3	3	1
#27	$w_{13}^{27} = w_{12}^{27} = 19.835570$	1	3	3	3
#28	$w_{13}^{28} = w_{12}^{28} = 10.759227$	2	1	1	1
#55	$w_{13}^{55} = w_{12}^{55} = 15.533485$	3	1	1	1
#57	$w_{13}^{57} = w_{12}^{57} = 5.538309$	3	1	1	3
#61	$w_{13}^{61} = w_{12}^{61} = 13.130227$	3	1	3	1
#63	$w_{13}^{63} = w_{12}^{63} = 6.056291$	3	1	3	3
#73	$w_{13}^{73} = w_{12}^{73} = 23.992772$	3	3	1	1
#75	$w_{13}^{75} = w_{12}^{75} = 16.699207$	3	3	1	3
#79	$w_{13}^{79} = w_{12}^{79} = 98.165759$	3	3	3	1
#81	$w_{13}^{81} = w_{12}^{81} = 129.664430$	3	3	3	3
	460.000000				

Step 14

We now apply proportional completion to voting pattern #4. In voting pattern #4, the voters are indifferent between the alternatives in $\{a, e\}$. At stage 1, $Y := w_1^4 + w_1^5 + w_1^{13} + w_1^{14} + w_1^{31} + w_1^{32} + w_1^{40} + w_1^{41} = 70$ voters were indifferent between all the alternatives in $\{a, e\}$. The following $N - Y = 390$ voters were not indifferent between all the alternatives in $\{a, e\}$:

number of voters	e
$w_1^1 + w_1^2 + w_1^3 + w_1^{10} + w_1^{11} + w_1^{19} + w_1^{21} + w_1^{28} + w_1^{29} + w_1^{37} + w_1^{38} + w_1^{55} + w_1^{57} + w_1^{73} + w_1^{75} = 129$	1
$w_1^7 + w_1^9 + w_1^{25} + w_1^{27} + w_1^{61} + w_1^{63} + w_1^{79} + w_1^{81} = 261$	3
$N - Y = 390$	

Therefore, the $w_{13}^4 = 5.909964$ voters with voting pattern #4 are replaced by the following voters:

voting pattern	number of voters	b	c	e	j
#1	$(w_1^1 + w_1^2 + w_1^3 + w_1^{10} + w_1^{11} + w_1^{19} + w_1^{21} + w_1^{28} + w_1^{29} + w_1^{37} + w_1^{38} + w_1^{55} + w_1^{57} + w_1^{73} + w_1^{75}) \cdot w_{13}^4 / (N - Y) = 1.954834$	1	1	1	1
#7	$(w_1^7 + w_1^9 + w_1^{25} + w_1^{27} + w_1^{61} + w_1^{63} + w_1^{79} + w_1^{81}) \cdot w_{13}^4 / (N - Y) = 3.955130$	1	1	3	1
	$w_{13}^4 = 5.909964$				

Therefore, we get:

voting pattern	number of voters	b	c	e	j
#1	$w_{14}^1 = w_{13}^1 + 1.954834 = 30.417386$	1	1	1	1
#3	$w_{14}^3 = w_{13}^3 = 5.481150$	1	1	1	3
#7	$w_{14}^7 = w_{13}^7 + 3.955130 = 13.279131$	1	1	3	1
#9	$w_{14}^9 = w_{13}^9 = 4.859413$	1	1	3	3
#10	$w_{14}^{10} = w_{13}^{10} = 12.008462$	1	2	1	1
#19	$w_{14}^{19} = w_{13}^{19} = 26.232914$	1	3	1	1
#21	$w_{14}^{21} = w_{13}^{21} = 5.490934$	1	3	1	3
#25	$w_{14}^{25} = w_{13}^{25} = 22.855333$	1	3	3	1
#27	$w_{14}^{27} = w_{13}^{27} = 19.835570$	1	3	3	3
#28	$w_{14}^{28} = w_{13}^{28} = 10.759227$	2	1	1	1
#55	$w_{14}^{55} = w_{13}^{55} = 15.533485$	3	1	1	1
#57	$w_{14}^{57} = w_{13}^{57} = 5.538309$	3	1	1	3
#61	$w_{14}^{61} = w_{13}^{61} = 13.130227$	3	1	3	1
#63	$w_{14}^{63} = w_{13}^{63} = 6.056291$	3	1	3	3
#73	$w_{14}^{73} = w_{13}^{73} = 23.992772$	3	3	1	1
#75	$w_{14}^{75} = w_{13}^{75} = 16.699207$	3	3	1	3
#79	$w_{14}^{79} = w_{13}^{79} = 98.165759$	3	3	3	1
#81	$w_{14}^{81} = w_{13}^{81} = 129.664430$	3	3	3	3
	460.000000				

Step 15

We now apply proportional completion to voting pattern #10. In voting pattern #10, the voters are indifferent between the alternatives in $\{a, c\}$. At stage 1, $Y := w_1^{10} + w_1^{11} + w_1^{13} + w_1^{14} + w_1^{37} + w_1^{38} + w_1^{40} + w_1^{41} = 89$ voters were indifferent between all the alternatives in $\{a, c\}$. The following $N - Y = 371$ voters were not indifferent between all the alternatives in $\{a, c\}$:

number of voters	c
$w_1^1 + w_1^2 + w_1^3 + w_1^4 + w_1^5 + w_1^7 + w_1^9 + w_1^{28} + w_1^{29} + w_1^{31} + w_1^{32} + w_1^{55} + w_1^{57} + w_1^{61} + w_1^{63} = 87$	1
$w_1^{19} + w_1^{21} + w_1^{25} + w_1^{27} + w_1^{73} + w_1^{75} + w_1^{79} + w_1^{81} = 284$	3
$N - Y = 371$	

Therefore, the $w_{14}^{10} = 12.008462$ voters with voting pattern #10 are replaced by the following voters:

voting pattern	number of voters	b	c	e	j
#1	$(w_1^1 + w_1^2 + w_1^3 + w_1^4 + w_1^5 + w_1^7 + w_1^9 + w_1^{28} + w_1^{29} + w_1^{31} + w_1^{32} + w_1^{55} + w_1^{57} + w_1^{61} + w_1^{63}) \cdot w_{14}^{10} / (N - Y) = 2.816001$	1	1	1	1
#19	$(w_1^{19} + w_1^{21} + w_1^{25} + w_1^{27} + w_1^{73} + w_1^{75} + w_1^{79} + w_1^{81}) \cdot w_{14}^{10} / (N - Y) = 9.192461$	1	3	1	1
	$w_{14}^{10} = 12.008462$				

Therefore, we get:

voting pattern	number of voters	b	c	e	j
#1	$w_{15}^1 = w_{14}^1 + 2.816001 = 33.233387$	1	1	1	1
#3	$w_{15}^3 = w_{14}^3 = 5.481150$	1	1	1	3
#7	$w_{15}^7 = w_{14}^7 = 13.279131$	1	1	3	1
#9	$w_{15}^9 = w_{14}^9 = 4.859413$	1	1	3	3
#19	$w_{15}^{19} = w_{14}^{19} + 9.192461 = 35.425375$	1	3	1	1
#21	$w_{15}^{21} = w_{14}^{21} = 5.490934$	1	3	1	3
#25	$w_{15}^{25} = w_{14}^{25} = 22.855333$	1	3	3	1
#27	$w_{15}^{27} = w_{14}^{27} = 19.835570$	1	3	3	3
#28	$w_{15}^{28} = w_{14}^{28} = 10.759227$	2	1	1	1
#55	$w_{15}^{55} = w_{14}^{55} = 15.533485$	3	1	1	1
#57	$w_{15}^{57} = w_{14}^{57} = 5.538309$	3	1	1	3
#61	$w_{15}^{61} = w_{14}^{61} = 13.130227$	3	1	3	1
#63	$w_{15}^{63} = w_{14}^{63} = 6.056291$	3	1	3	3
#73	$w_{15}^{73} = w_{14}^{73} = 23.992772$	3	3	1	1
#75	$w_{15}^{75} = w_{14}^{75} = 16.699207$	3	3	1	3
#79	$w_{15}^{79} = w_{14}^{79} = 98.165759$	3	3	3	1
#81	$w_{15}^{81} = w_{14}^{81} = 129.664430$	3	3	3	3
	460.000000				

Step 16

We now apply proportional completion to voting pattern #28. In voting pattern #28, the voters are indifferent between the alternatives in $\{a, b\}$. At stage 1, $Y := w_1^{28} + w_1^{29} + w_1^{31} + w_1^{32} + w_1^{37} + w_1^{38} + w_1^{40} + w_1^{41} = 73$ voters were indifferent between all the alternatives in $\{a, b\}$. The following $N - Y = 387$ voters were not indifferent between all the alternatives in $\{a, b\}$:

number of voters	b
$w_1^1 + w_1^2 + w_1^3 + w_1^4 + w_1^5 + w_1^7 + w_1^9 + w_1^{10} + w_1^{11} + w_1^{13} + w_1^{14} + w_1^{19} + w_1^{21} + w_1^{25} + w_1^{27} = 121$	1
$w_1^{55} + w_1^{57} + w_1^{61} + w_1^{63} + w_1^{73} + w_1^{75} + w_1^{79} + w_1^{81} = 266$	3
$N - Y = 387$	

Therefore, the $w_{15}^{28} = 10.759227$ voters with voting pattern #28 are replaced by the following voters:

voting pattern	number of voters	b	c	e	j
#1	$(w_1^1 + w_1^2 + w_1^3 + w_1^4 + w_1^5 + w_1^7 + w_1^9 + w_1^{10} + w_1^{11} + w_1^{13} + w_1^{14} + w_1^{19} + w_1^{21} + w_1^{25} + w_1^{27}) \cdot w_{15}^{28} / (N - Y) = 3.363996$	1	1	1	1
#55	$(w_1^{55} + w_1^{57} + w_1^{61} + w_1^{63} + w_1^{73} + w_1^{75} + w_1^{79} + w_1^{81}) \cdot w_{15}^{28} / (N - Y) = 7.395231$	3	1	1	1
	$w_{15}^{28} = 10.759227$				

Therefore, we get:

voting pattern	number of voters	b	c	e	j
#1	$w_{16}^1 = w_{15}^1 + 3.363996 = 36.597383$	1	1	1	1
#3	$w_{16}^3 = w_{15}^3 = 5.481150$	1	1	1	3
#7	$w_{16}^7 = w_{15}^7 = 13.279131$	1	1	3	1
#9	$w_{16}^9 = w_{15}^9 = 4.859413$	1	1	3	3
#19	$w_{16}^{19} = w_{15}^{19} = 35.425375$	1	3	1	1
#21	$w_{16}^{21} = w_{15}^{21} = 5.490934$	1	3	1	3
#25	$w_{16}^{25} = w_{15}^{25} = 22.855333$	1	3	3	1
#27	$w_{16}^{27} = w_{15}^{27} = 19.835570$	1	3	3	3
#55	$w_{16}^{55} = w_{15}^{55} + 7.395231 = 22.928716$	3	1	1	1
#57	$w_{16}^{57} = w_{15}^{57} = 5.538309$	3	1	1	3
#61	$w_{16}^{61} = w_{15}^{61} = 13.130227$	3	1	3	1
#63	$w_{16}^{63} = w_{15}^{63} = 6.056291$	3	1	3	3
#73	$w_{16}^{73} = w_{15}^{73} = 23.992772$	3	3	1	1
#75	$w_{16}^{75} = w_{15}^{75} = 16.699207$	3	3	1	3
#79	$w_{16}^{79} = w_{15}^{79} = 98.165759$	3	3	3	1
#81	$w_{16}^{81} = w_{15}^{81} = 129.664430$	3	3	3	3
	460.000000				

8.2.2. Links between Sets of Alternatives

In section 8.2.2, we will show how the strengths of the links are calculated.

According to (8.1.2.1), the strength of the link $(\{a_1, \dots, a_{(M-1)}\}; b) \rightarrow (\{a_1, \dots, a_{(M-1)}\}; c)$ is given by $(N[\{a_1, \dots, a_{(M-1)}\}; b]; c]$, $N[\{a_1, \dots, a_{(M-1)}\}; c]; b]$, where $N[\{a_1, \dots, a_{(M-1)}\}; b]; c]$ is the support and $N[\{a_1, \dots, a_{(M-1)}\}; c]; b]$ is the opposition of this link.

$N[\{a_1, \dots, a_M\}; g]$ is defined as follows:

$N[\{a_1, \dots, a_M\}; g] \in \mathbb{R}_{\geq 0}$ is the largest value such that there is a $t \in \mathbb{R}^{(N_W \times M)}$ such that:

$$(8.1.2.2) \quad \forall i \in \{1, \dots, N_W\} \quad \forall j \in \{1, \dots, M\}: t_{ij} \geq 0.$$

$$(8.1.2.3) \quad \forall i \in \{1, \dots, N_W\}: \sum_{j=1}^M t_{ij} \leq \rho(i).$$

$$(8.1.2.4) \quad \forall i \in \{1, \dots, N_W\} \quad \forall j \in \{1, \dots, M\}: g \succ_i a_j \Rightarrow t_{ij} = 0.$$

$$(8.1.2.5) \quad \forall j \in \{1, \dots, M\}: \sum_{i=1}^{N_W} t_{ij} \geq N[\{a_1, \dots, a_M\}; g].$$

Suppose $N^*[\{a_1, \dots, a_M\}; g] \in \mathbb{R}_{\geq 0}$ is the largest value such that there is a $t^* \in \mathbb{R}^{(N_W \times M)}$ such that:

$$(8.2.2.1) \quad \forall i \in \{1, \dots, N_W\} \quad \forall j \in \{1, \dots, M\}: t_{ij}^* \geq 0.$$

$$(8.2.2.2) \quad \forall i \in \{1, \dots, N_W\}: \sum_{j=1}^M t_{ij}^* \leq \rho(i).$$

$$(8.2.2.3) \quad \forall i \in \{1, \dots, N_W\} \quad \forall j \in \{1, \dots, M\}: g \succ_i a_j \Rightarrow t_{ij}^* = 0.$$

$$(8.2.2.4) \quad \sum_{i=1}^{N_W} \sum_{j=1}^M t_{ij}^* \geq M \cdot N^*[\{a_1, \dots, a_M\}; g].$$

As (8.2.2.4) is weaker than (8.1.2.5), we get:

$$N[\{a_1, \dots, a_M\}; g] \leq N^*[\{a_1, \dots, a_M\}; g].$$

Suppose $t^* \in \mathbb{R}^{(N_W \times M)}$ is a solution of (8.2.2.1) – (8.2.2.4). Then we define:

$$N^\wedge[\{a_1, \dots, a_M\}; g] := \min \left\{ \sum_{i=1}^{N_W} t_{ij}^* \mid 1 \leq j \leq M \right\}.$$

So we get:

$$N^\wedge[\{a_1, \dots, a_M\}; g] \leq N[\{a_1, \dots, a_M\}; g] \leq N^*[\{a_1, \dots, a_M\}; g].$$

Compared to (8.1.2.2) – (8.1.2.5), (8.2.2.1) – (8.2.2.4) has the advantage that it describes a trivial max-flow problem. A max-flow problem can be solved significantly faster than a general linear program. Therefore, we solve (8.1.2.2) – (8.1.2.5) by solving a series of max-flow problems as follows:

Suppose $\mathfrak{W}$ is the number of voters who strictly prefer candidate g to every candidate of the set $\{a_1, \dots, a_M\}$. Then we know that $N[\{a_1, \dots, a_M\}; g]$ cannot be larger than $(N - \mathfrak{W}) / M$.

Therefore, we start with

$$r^{(0)} := (N - \mathfrak{W}) / M.$$

$$s^{(0)} := 0.$$

For $z = 1, 2, 3, \dots$, we solve the following linear programs $\text{LP}^{(z)}$:

Find the maximum $r^{(z)} \in \mathbb{R}$ such that there is a $t^{(z)} \in \mathbb{R}^{(N_W \times M)}$ such that

$$(8.2.2.5) \quad \forall i \in \{1, \dots, N_W\} \quad \forall j \in \{1, \dots, M\}: t_{ij}^{(z)} \geq 0.$$

$$(8.2.2.6) \quad \forall i \in \{1, \dots, N_W\}: \sum_{j=1}^M t_{ij}^{(z)} \leq \rho(i).$$

$$(8.2.2.7) \quad \forall i \in \{1, \dots, N_W\} \quad \forall j \in \{1, \dots, M\}: g \succ_i a_j \Rightarrow t_{ij}^{(z)} = 0.$$

$$(8.2.2.8) \quad \sum_{i=1}^{N_W} \sum_{j=1}^M t_{ij}^{(z)} \geq M \cdot r^{(z)}.$$

$$(8.2.2.9) \quad \forall j \in \{1, \dots, M\}: \sum_{i=1}^{N_W} t_{ij}^{(z)} \leq r^{(z-1)}.$$

Furthermore, we define for $z = 1, 2, 3, \dots$:

$$(8.2.2.10) \quad s^{(z)} := \max \{ s^{(z-1)}, \min \{ \sum_{i=1}^{N_W} t_{ij}^{(z)} \mid 1 \leq j \leq M \} \}.$$

When we solve (8.2.2.5) – (8.2.2.9), then we get a decreasing sequence $r^{(0)}, r^{(1)}, r^{(2)}, r^{(3)}, \dots$ and an increasing sequence $s^{(0)}, s^{(1)}, s^{(2)}, s^{(3)}, \dots$. These two sequences converge to the same limit. This limit is the solution of (8.1.2.2) – (8.1.2.5).

Now, we use this algorithm to calculate the support of link $\{b,c,e,j\} \rightarrow (\{b,c,e\};a)$ which is identical to the support of links $\{b,c,e,j\} \rightarrow (\{b,c,j\};a)$, $\{b,c,e,j\} \rightarrow (\{b,e,j\};a)$ and $\{b,c,e,j\} \rightarrow (\{c,e,j\};a)$. After proportional completion, the voter profile looks as follows:

		b	c	e	j
voter01	36.597383	1	1	1	1
voter02	5.481150	1	1	1	3
voter03	13.279131	1	1	3	1
voter04	4.859413	1	1	3	3
voter05	35.425375	1	3	1	1
voter06	5.490934	1	3	1	3
voter07	22.855333	1	3	3	1
voter08	19.835570	1	3	3	3
voter09	22.928716	3	1	1	1
voter10	5.538309	3	1	1	3
voter11	13.130227	3	1	3	1
voter12	6.056291	3	1	3	3
voter13	23.992772	3	3	1	1
voter14	16.699207	3	3	1	3
voter15	98.165759	3	3	3	1
voter16	129.664430	3	3	3	3
	460.000000				

The corresponding max-flow problem has the following form:

Each voting pattern, where voters strictly prefer at least one alternative of the set $\{b,c,e,j\}$ to alternative a , is represented by a vertex. Each alternative of the set $\{b,c,e,j\}$ is represented by a vertex. Furthermore, there is a vertex “source” and a vertex “drain”.

From the vertex “source” we draw a link to each vertex that represents a voting pattern. The maximum capacity of this link is the number of voters with this voting pattern.

From each vertex, that represents a voting pattern, we draw a link to each vertex that represents an alternative that is strictly preferred to alternative a by voters with this voting pattern. The maximum capacity of this link is the number of voters with this voting pattern.

From each vertex, that represents an alternative, we draw a link to the vertex “drain”. The maximum capacity of this link is $r^{(z-1)}$.

The task is: Maximize the total flow from the vertex “source” to the vertex “drain”.

In our case, we get a digraph with 21 vertices and 51 links.

Furthermore, we get:

$$r^{(0)} := (N - \mathbf{w}) / M = (460 - 129.664430) / 4 = 82.583893$$

Our digraph has the following form:

link	start	end	capacity
1	source	voter01	36.597383
2	source	voter02	5.481150
3	source	voter03	13.279131
4	source	voter04	4.859413
5	source	voter05	35.425375
6	source	voter06	5.490934

32	voter06	alternative e	5.490934
33	voter07	alternative b	22.855333
34	voter07	alternative j	22.855333
35	voter08	alternative b	19.835570
36	voter09	alternative c	22.928716
37	voter09	alternative e	22.928716
38	voter09	alternative j	22.928716
39	voter10	alternative c	5.538309
40	voter10	alternative e	5.538309
41	voter11	alternative c	13.130227
42	voter11	alternative j	13.130227
43	voter12	alternative c	6.056291
44	voter13	alternative e	23.992772
45	voter13	alternative j	23.992772
46	voter14	alternative e	16.699207
47	voter15	alternative j	98.165759
48	alternative b	drain	$r^{(z-1)}$
49	alternative c	drain	$r^{(z-1)}$
50	alternative e	drain	$r^{(z-1)}$
51	alternative j	drain	$r^{(z-1)}$

The following 13 pages document the solutions for (8.2.2.5) – (8.2.2.10). Those entries that change from one table to the next table are **fat and underlined**.

We get:

$$\begin{array}{ll}
 r^{(0)} = 82.583893; & s^{(0)} = 0.000000 \\
 r^{(1)} = 78.688426; & s^{(1)} = 71.469640 \\
 r^{(2)} = 77.714559; & s^{(2)} = 75.365107 \\
 r^{(3)} = 77.471093; & s^{(3)} = 76.740693 \\
 r^{(4)} = 77.410226; & s^{(4)} = 77.227626 \\
 r^{(5)} = 77.395009; & s^{(5)} = 77.349359 \\
 r^{(6)} = 77.391205; & s^{(6)} = 77.379793 \\
 r^{(7)} = 77.390254; & s^{(7)} = 77.387401 \\
 r^{(8)} = 77.390016; & s^{(8)} = 77.389303 \\
 r^{(9)} = 77.389957; & s^{(9)} = 77.389779 \\
 r^{(10)} = 77.389942; & s^{(10)} = 77.389897 \\
 r^{(11)} = 77.389938; & s^{(11)} = 77.389927 \\
 r^{(12)} = 77.389937; & s^{(12)} = 77.389935
 \end{array}$$

We get:

$$r = \lim_{z \rightarrow \infty} r^{(z)} = \lim_{z \rightarrow \infty} s^{(z)} = 77.389937$$

Stage $z = 1$:

link	start	end	capacity	flow

Table 8.2.2.1 (part 2 of 2): Voting patterns and allocation of votes in example A53

8.2.3. Applying the Schulze Tie-Breaking Method

Table 8.2.3.1 lists the links in example A53.

11	<i>a</i>	<i>b</i>	<i>c</i>	<i>e</i>	<i>j</i>	77.389937	99.563758	107.281879	101.107383	69.463087

For example, row 11 of table 8.2.3.1 contains the following information:

- $N[\{b, c, e, j\}; a] = 77.389937$
- $N[\{a, c, e, j\}; b] = 99.563758$
- $N[\{a, b, e, j\}; c] = 107.281879$
- $N[\{a, b, c, j\}; e] = 101.107383$
- $N[\{a, b, c, e\}; j] = 69.463087$

- The link $\{b, c, e, j\} \rightarrow \{a, c, e, j\}$ has a strength of $(N[\{b, c, e, j\}; a], N[\{a, c, e, j\}; b])$.
- The link $\{b, c, e, j\} \rightarrow \{a, b, e, j\}$ has a strength of $(N[\{b, c, e, j\}; a], N[\{a, b, e, j\}; c])$.
- The link $\{b, c, e, j\} \rightarrow \{a, b, c, j\}$ has a strength of $(N[\{b, c, e, j\}; a], N[\{a, b, c, j\}; e])$.
- The link $\{b, c, e, j\} \rightarrow \{a, b, c, e\}$ has a strength of $(N[\{b, c, e, j\}; a], N[\{a, b, c, e\}; j])$.

- The link $\{a, c, e, j\} \rightarrow \{b, c, e, j\}$ has a strength of $(N[\{a, c, e, j\}; b], N[\{b, c, e, j\}; a])$.
- The link $\{a, c, e, j\} \rightarrow \{a, b, e, j\}$ has a strength of $(N[\{a, c, e, j\}; b], N[\{a, b, e, j\}; c])$.
- The link $\{a, c, e, j\} \rightarrow \{a, b, c, j\}$ has a strength of $(N[\{a, c, e, j\}; b], N[\{a, b, c, j\}; e])$.
- The link $\{a, c, e, j\} \rightarrow \{a, b, c, e\}$ has a strength of $(N[\{a, c, e, j\}; b], N[\{a, b, c, e\}; j])$.

- The link $\{a, b, e, j\} \rightarrow \{b, c, e, j\}$ has a strength of $(N[\{a, b, e, j\}; c], N[\{b, c, e, j\}; a])$.
- The link $\{a, b, e, j\} \rightarrow \{a, c, e, j\}$ has a strength of $(N[\{a, b, e, j\}; c], N[\{a, c, e, j\}; b])$.
- The link $\{a, b, e, j\} \rightarrow \{a, b, c, j\}$ has a strength of $(N[\{a, b, e, j\}; c], N[\{a, b, c, j\}; e])$.
- The link $\{a, b, e, j\} \rightarrow \{a, b, c, e\}$ has a strength of $(N[\{a, b, e, j\}; c], N[\{a, b, c, e\}; j])$.

- The link $\{a, b, c, j\} \rightarrow \{b, c, e, j\}$ has a strength of $(N[\{a, b, c, j\}; e], N[\{b, c, e, j\}; a])$.
- The link $\{a, b, c, j\} \rightarrow \{a, c, e, j\}$ has a strength of $(N[\{a, b, c, j\}; e], N[\{a, c, e, j\}; b])$.
- The link $\{a, b, c, j\} \rightarrow \{a, b, e, j\}$ has a strength of $(N[\{a, b, c, j\}; e], N[\{a, b, e, j\}; c])$.
- The link $\{a, b, c, j\} \rightarrow \{a, b, c, e\}$ has a strength of $(N[\{a, b, c, j\}; e], N[\{a, b, c, e\}; j])$.

- The link $\{a, b, c, e\} \rightarrow \{b, c, e, j\}$ has a strength of $(N[\{a, b, c, e\}; j], N[\{b, c, e, j\}; a])$.
- The link $\{a, b, c, e\} \rightarrow \{a, c, e, j\}$ has a strength of $(N[\{a, b, c, e\}; j], N[\{a, c, e, j\}; b])$.
- The link $\{a, b, c, e\} \rightarrow \{a, b, e, j\}$ has a strength of $(N[\{a, b, c, e\}; j], N[\{a, b, e, j\}; c])$.
- The link $\{a, b, c, e\} \rightarrow \{a, b, c, j\}$ has a strength of $(N[\{a, b, c, e\}; j], N[\{a, b, c, j\}; e])$.

So, row 11 of table 8.2.3.1 represents the following links:

When we apply the Schulze tie-breaker, as defined at stage 3 of section 8.1.3, to the links of table 8.2.3.1 with $>_{\text{margin}}$ for $>_{D2}$, we get $\{a, d, g, j\}$ as winning set.

For example, we have:

- Line 33: The link $\{a, b, g, j\} \rightarrow \{a, d, g, j\}$ has a strength of $(N[\{a, b, g, j\}; d], N[\{a, d, g, j\}; b]) = (101.411379, 102.166302)$.
- Line 33: The link $\{a, d, g, j\} \rightarrow \{a, b, g, j\}$ has a strength of $(N[\{a, d, g, j\}; b], N[\{a, b, g, j\}; d]) = (102.166302, 101.411379)$.
- Line 49: The link $\{a, b, g, j\} \rightarrow \{a, f, g, j\}$ has a strength of $(N[\{a, b, g, j\}; f], N[\{a, f, g, j\}; b]) = (101.068282, 102.334802)$.
- Line 49: The link $\{a, f, g, j\} \rightarrow \{a, b, g, j\}$ has a strength of $(N[\{a, f, g, j\}; b], N[\{a, b, g, j\}; f]) = (102.334802, 101.068282)$.
- Line 104: The link $\{a, d, g, j\} \rightarrow \{a, f, g, j\}$ has a strength of $(N[\{a, d, g, j\}; f], N[\{a, f, g, j\}; d]) = (101.351648, 101.098901)$.
- Line 104: The link $\{a, f, g, j\} \rightarrow \{a, d, g, j\}$ has a strength of $(N[\{a, f, g, j\}; d], N[\{a, d, g, j\}; f]) = (101.098901, 101.351648)$.

So $\{a, d, g, j\}$ beats $\{a, b, g, j\}$ in the direct comparison, $\{a, f, g, j\}$ beats $\{a, b, g, j\}$ in the direct comparison, and $\{a, d, g, j\}$ beats $\{a, f, g, j\}$ in the direct comparison.

When there are C alternatives, then there are $(C!)/(((M+1)!)\cdot((C-M-1)!))$ possible $(M+1)$ -way contests. For $C = 10$ and $M = 4$, we get 252 possible 5-way contests. Table 8.2.3.1 lists these 252 possible 5-way contests for example A53.

When Schulze STV is used to choose M from $(M+1)$ alternatives $\{a_1, \dots, a_{(M+1)}\}$, then that alternative $k \in \{1, \dots, (M+1)\}$ is eliminated for which $N[(\{a_1, \dots, a_{(M+1)}\} \setminus \{a_k\}); a_k]$ is the maximum, while the other M alternatives are elected. In table 8.2.3.1, the maximum $N[(\{a_1, \dots, a_{(M+1)}\} \setminus \{a_k\}); a_k]$ of each 5-way contest is **fat and underlined**.

Suppose the maximum $N[(\{a_1, \dots, a_{(M+1)}\} \setminus \{a_k\}); a_k]$ of a $(M+1)$ -way contest is not unique. Suppose $1 < m \leq (M+1)$ entries are tied for maximum $N[(\{a_1, \dots, a_{(M+1)}\} \setminus \{a_k\}); a_k]$, then the m alternatives with maximum $N[(\{a_1, \dots, a_{(M+1)}\} \setminus \{a_k\}); a_k]$ are tied for winning one of the remaining $(m-1)$ seats, while the other $(M+1-m)$ alternatives are elected. In table 8.2.3.1 for those 5-way contests, where the maximum $N[(\{a_1, \dots, a_{(M+1)}\} \setminus \{a_k\}); a_k]$ is not unique, those $N[(\{a_1, \dots, a_{(M+1)}\} \setminus \{a_k\}); a_k]$, that are tied for maximum $N[(\{a_1, \dots, a_{(M+1)}\} \setminus \{a_k\}); a_k]$, are *italic and underlined* (only lines 27, 149, and 155).

In table 8.2.3.1, we see:

- Alternatives a , g , and j each win in every 5-way contest.
- Alternative d is tied for winning in one 5-way contest (line 27) and wins in every other 5-way contest.
- Alternative f loses in one 5-way contest (line 104) and wins in every other 5-way contest.
- Alternative b wins in 121 5-way contests, is tied for winning in one 5-way contest (line 27), and loses in four 5-way contests (lines 30, 33, 49, and 174).
- Alternative e wins 111 times and loses 15 times.
- Alternative h wins 59 times and loses 67 times.
- Alternative c wins 45 times, is tied twice (lines 149 and 155), and loses 79 times.
- Alternative i wins 41 times, is tied twice (lines 149 and 155), and loses 83 times.

8.3. Condorcet Criterion for Multi-Winner Elections

In this section, we will propose a generalization of the Condorcet criterion to multi-winner elections. The Condorcet criterion for single-winner elections (section 4.8) is important because, when there is a Condorcet winner $b \in A$, then it is still a Condorcet winner when alternatives $a_1, \dots, a_n \in A \setminus \{b\}$ are removed. So an alternative $b \in A$ doesn't owe his property of being a Condorcet winner to the presence of some other alternatives. Therefore, when we declare a Condorcet winner $b \in A$ elected whenever a Condorcet winner exists, we know that no other alternatives $a_1, \dots, a_n \in A \setminus \{b\}$ have changed the result of the election without being elected.

Therefore, a generalization of the Condorcet criterion to multi-winner elections should have the following properties:

- It should not be possible that there are more than M Condorcet winners (where M is the number of seats). This property is important because the Condorcet winners will later be declared the winners.
- Suppose $b \in A$ is a Condorcet winner. Then it should still be a Condorcet winner when alternatives $a_1, \dots, a_n \in A \setminus \{b\}$ are removed.
- The requirement for being a Condorcet winner should be as weak as possible, so that there are as many Condorcet winners as possible, so that the resulting Condorcet criterion becomes as strong as possible.

We propose the following generalization:

(8.3.1) In multi-winner elections, a *Condorcet winner* is an alternative $b \in A$ that wins in every $(M+1)$ -way contest. Suppose $\mathcal{S}_{M|B}$ (with $\emptyset \neq \mathcal{S}_{M|B} \subseteq A_M$) is the set of potential winning sets when the used method to fill M seats is applied to the set B (with $\emptyset \neq B \subseteq A$ and $\|B\| > M$). Then we get:

(8.3.1a) $b \in A$ is a *Condorcet winner* : $\Leftrightarrow$

$\forall \emptyset \neq B \subseteq A$ with $b \in B$ and $\|B\| = (M+1) \forall \mathcal{A} \in \mathcal{S}_{M|B}: b \in \mathcal{A}$.

The *Condorcet criterion* says that, when there is a Condorcet winner, then it should also be a winner overall. In short:

(8.3.1b) $b \in A$ is a Condorcet winner. $\Rightarrow (\forall \mathcal{A} \in \mathcal{S}_M: b \in \mathcal{A}.)$

When $\succ_D$ satisfies (2.1.5) then for $M = 1$:

- (8.3.1a) is identical to (4.8.6) and (4.12.1.1).
- (8.3.1b) is identical to (4.8.7)(i).

(8.3.2) In multi-winner elections, a *weak Condorcet winner* is an alternative $b \in A$ that wins or is tied for winning/losing in every $(M+1)$ -way contest. In short:

(8.3.2a) $b \in A$ is a *weak Condorcet winner* : $\Leftrightarrow$

$\forall \emptyset \neq B \subseteq A$ with $b \in B$ and $\| B \| = (M+1) \exists \mathcal{A} \in \mathcal{S}_{M|B} : b \in \mathcal{A}.$

A weak Condorcet winner should win or be tied for winning/losing overall. In short:

(8.3.2b) $b \in A$ is a weak Condorcet winner. $\Rightarrow (\exists \mathcal{A} \in \mathcal{S}_M : b \in \mathcal{A}.)$

When $\succ_D$ satisfies (2.1.4) and (2.1.5) then for $M = 1$:

- (8.3.2a) is identical to (4.12.1.2).
- (8.3.2b) is identical to (4.12.1.6).

(8.3.3) In multi-winner elections, A *Condorcet loser* is an alternative $b \in A$ that loses in every $(M+1)$ -way contest. In short:

(8.3.3a) $b \in A$ is a *Condorcet loser* : $\Leftrightarrow$

$\forall \emptyset \neq B \subseteq A$ with $b \in B$ and $\| B \| = (M+1) \forall \mathcal{A} \in \mathcal{S}_{M|B} : b \notin \mathcal{A}.$

A Condorcet loser should be a loser overall. In short:

(8.3.3b) $b \in A$ is a Condorcet loser. $\Rightarrow (\forall \mathcal{A} \in \mathcal{S}_M : b \notin \mathcal{A}.)$

When $\succ_D$ satisfies (2.1.5) then for $M = 1$:

- (8.3.3a) is identical to (4.8.8) and (4.12.2.1).
- (8.3.3b) is identical to (4.8.9)(i).

(8.3.4) In multi-winner elections, a *weak Condorcet loser* is an alternative $b \in A$ that loses or is tied for winning/losing in every $(M+1)$ -way contest. In short:

(8.3.4a) $b \in A$ is a *weak Condorcet loser* : $\Leftrightarrow$

$\forall \emptyset \neq B \subseteq A$ with $b \in B$ and $\| B \| = (M+1) \exists \mathcal{A} \in \mathcal{S}_{M|B} : b \notin \mathcal{A}.$

A weak Condorcet loser should lose or be tied for winning/losing overall. In short:

(8.3.4b) $b \in A$ is a weak Condorcet loser. $\Rightarrow (\exists \mathcal{A} \in \mathcal{S}_M : b \notin \mathcal{A}.)$

When $\succ_D$ satisfies (2.1.4) and (2.1.5) then for $M = 1$:

- (8.3.4a) is identical to (4.12.2.2).
- (8.3.4b) is identical to (4.12.2.13).

It is important to keep in mind that, in multi-winner elections, the terms “Condorcet winner”, “weak Condorcet winner”, “Condorcet loser”, and “weak Condorcet loser” always refer to the specific election method. For example, plurality-at-large will lead to different Condorcet winners than an STV method. So in multi-winner elections, the Condorcet criterion rather refers to the inner logic of the specific election method than to alternatives that must be elected regardless of the election method used.

If $>_{D_2}$ satisfies (2.1.4) and (2.1.5), then we get for Schulze STV:

$$(8.3.5) \quad b \in A \text{ is a Condorcet winner} \Leftrightarrow \\ \forall \{a_1, \dots, a_M\} \subseteq A \setminus \{b\} \exists a_i \in \{a_1, \dots, a_M\}: \\ N[\{a_1, \dots, a_M\}; b] < N[(\{a_1, \dots, a_M, b\} \setminus \{a_i\}); a_i].$$

$$(8.3.6) \quad b \in A \text{ is a weak Condorcet winner} \Leftrightarrow \\ \forall \{a_1, \dots, a_M\} \subseteq A \setminus \{b\} \exists a_i \in \{a_1, \dots, a_M\}: \\ N[\{a_1, \dots, a_M\}; b] \leq N[(\{a_1, \dots, a_M, b\} \setminus \{a_i\}); a_i].$$

$$(8.3.7) \quad b \in A \text{ is a Condorcet loser} \Leftrightarrow \\ \forall \{a_1, \dots, a_M\} \subseteq A \setminus \{b\} \forall a_i \in \{a_1, \dots, a_M\}: \\ N[\{a_1, \dots, a_M\}; b] > N[(\{a_1, \dots, a_M, b\} \setminus \{a_i\}); a_i].$$

$$(8.3.8) \quad b \in A \text{ is a weak Condorcet loser} \Leftrightarrow \\ \forall \{a_1, \dots, a_M\} \subseteq A \setminus \{b\} \forall a_i \in \{a_1, \dots, a_M\}: \\ N[\{a_1, \dots, a_M\}; b] \geq N[(\{a_1, \dots, a_M, b\} \setminus \{a_i\}); a_i].$$

In example A53, the alternatives a , g , and j win in every 5-way contest; therefore, these alternatives should also win overall. The alternative d is tied for winning in one case (line 27) and wins in every other case; therefore, this alternative should win or be tied for winning/losing overall.

While there can be up to M Condorcet winners, there cannot be more than one Condorcet loser.

Claim:

If $>_{D_2}$ satisfies (2.1.5), then Schulze STV, as defined in section 8.1, satisfies the Condorcet criterion for multi-winner elections, as defined in (8.3.1).

Proof:

Suppose alternative $b \in A$ is a Condorcet winner. Suppose $\{a_1, \dots, a_M\} \subseteq A \setminus \{b\}$.

We apply Schulze STV, as defined in section 8.1, on $\{a_1, \dots, a_M, b\}$. Suppose $c \in \{a_1, \dots, a_M, b\}$ is an alternative with maximum $N[(\{a_1, \dots, a_M, b\} \setminus \{c\}); c]$. Then $(N[(\{a_1, \dots, a_M, b\} \setminus \{c\}); c], N[\{a_1, \dots, a_M\}; b])$ is a win. With (8.3.5), we get that alternative c cannot be identical to alternative b . Therefore, the link $(\{a_1, \dots, a_M, b\} \setminus \{c\}) \rightarrow \{a_1, \dots, a_M\}$ is a path from $(\{a_1, \dots, a_M, b\} \setminus \{c\})$ to $\{a_1, \dots, a_M\}$ that contains only wins.

On the other side, there cannot be a path from $\{a_1, \dots, a_M\}$ to $(\{a_1, \dots, a_M, b\} \setminus \{c\})$ that contains only wins because any path from $\{a_1, \dots, a_M\}$ to $(\{a_1, \dots, a_M, b\} \setminus \{c\})$ must contain a link from a set $\mathcal{U}(i)$ with $b \notin \mathcal{U}(i)$ to a set $\mathcal{U}(i+1)$ with $b \in \mathcal{U}(i+1)$. But because of the definition of Condorcet winners, the link $\mathcal{U}(i) \rightarrow \mathcal{U}(i+1)$ must be a tie or a defeat.

With (2.1.5), we get that every path that contains only wins is stronger than every path that contains a tie or a defeat.

Therefore, every set $\{a_1, \dots, a_M\}$, that does not contain alternative b , is disqualified by some set that contains alternative b . $\square$

The proofs that Schulze STV satisfies (8.3.2b), (8.3.2c), and (8.3.2d) are analogue to the proofs for (4.12.1.6), (4.12.2.13), and (8.3.2a).

In a similar manner, we can generalize the Smith criterion (section 4.8) to multi-winner elections.

Definition:

A multi-winner election method, where M is the number of seats, satisfies the *Smith criterion for multi-winner elections*, if the following holds:

Suppose $\emptyset \neq B \subsetneq A$. Suppose $x \in \mathbb{N}$ with $1 \leq x \leq \|B\|$ and $x \leq M$.

(8.3.9) Suppose, for every $y \in \mathbb{N}$ with $1 \leq y \leq x$, we have: In every $(M+1)$ -contest between y alternatives of the set B and $M+1-y$ alternatives of $A \setminus B$ each of the alternatives of the set B is in every potential winning set.

Then every potential winning set contains at least x alternatives of the set B .

In short, a multi-winner election method, where M is the number of seats, satisfies the *Smith criterion for multi-winner elections*, if the following holds:

$$\begin{aligned}
 (8.3.10) \quad & \forall \emptyset \neq B \subsetneq A \quad \forall x \in \mathbb{N} \text{ with } 1 \leq x \leq \|B\| \text{ and } x \leq M: \\
 & ((\forall y \in \mathbb{N} \text{ with } 1 \leq y \leq x \\
 & \quad \forall \emptyset \neq \tilde{A} \subseteq A \text{ with } \|\tilde{A}\| = (M+1) \text{ and } \|\tilde{A} \cap B\| = y \\
 & \quad \forall \tilde{\mathcal{A}} \in \mathcal{S}_{M|\tilde{A}}: \|\tilde{\mathcal{A}} \cap B\| = y.) \\
 & \Rightarrow (\forall \mathcal{A} \in \mathcal{S}_M: \|\mathcal{A} \cap B\| \geq x.))
 \end{aligned}$$

So (8.3.10) basically says that, when all alternatives of the set B are elected whenever exactly y alternatives of the set B and exactly $M+1-y$ alternatives of $A \setminus B$ are running and when this is true for all $y \in \mathbb{N}$ with $1 \leq y \leq x$ (for some $x \in \mathbb{N}$ with $1 \leq x \leq \|B\|$ and $x \leq M$), then at least x alternatives of the set B must be elected. This means: Every potential winning set $\mathcal{A} \in \mathcal{S}_M$ must contain at least x alternatives of set B .

For $M = 1$, (8.3.10) is identical to (4.8.5), the Smith criterion for single-winner elections.

Claim:

If $\succ_{D2}$ satisfies (2.1.5), then Schulze STV, as defined in section 8.1, satisfies the Smith criterion for multi-winner elections.

Proof (overview):

The proof that Schulze STV satisfies the Smith criterion for multi-winner elections is analogous to the proof that Schulze STV satisfies the Condorcet criterion for multi-winner elections.

Part 1: Suppose $z \in \mathbb{N}_0$ with $0 \leq z < x$. Suppose $\{a_1, \dots, a_{(M-z)}, b_1, \dots, b_z\}$ is a set of $M-z$ alternatives $a_1, \dots, a_{(M-z)} \in A \setminus B$ and z alternatives $b_1, \dots, b_z \in B$. Suppose $b_{(z+1)} \in B \setminus \{b_1, \dots, b_z\}$ is an arbitrarily chosen alternative. Suppose $c \in \{a_1, \dots, a_{(M-z)}, b_1, \dots, b_z, b_{(z+1)}\}$ is an alternative with maximum $N[(\{a_1, \dots, a_{(M-z)}, b_1, \dots, b_z, b_{(z+1)}\} \setminus \{c\}); c]$. Then $(N[(\{a_1, \dots, a_{(M-z)}, b_1, \dots, b_z, b_{(z+1)}\} \setminus \{c\}); c], N[\{a_1, \dots, a_{(M-z)}, b_1, \dots, b_z, b_{(z+1)}\}; b_{(z+1)}])$ is a win. With (8.3.9), we get $c \notin \{b_1, \dots, b_z, b_{(z+1)}\}$. Therefore, the link $(\{a_1, \dots, a_{(M-z)}, b_1, \dots, b_z, b_{(z+1)}\} \setminus \{c\}) \rightarrow \{a_1, \dots, a_{(M-z)}, b_1, \dots, b_z\}$ is a path from $(\{a_1, \dots, a_{(M-z)}, b_1, \dots, b_z, b_{(z+1)}\} \setminus \{c\})$ to $\{a_1, \dots, a_{(M-z)}, b_1, \dots, b_z\}$ that contains only wins.

On the other side, there cannot be a path from $\{a_1, \dots, a_{(M-z)}, b_1, \dots, b_z\}$ to $(\{a_1, \dots, a_{(M-z)}, b_1, \dots, b_z, b_{(z+1)}\} \setminus \{c\})$ that contains only wins because any path from $\{a_1, \dots, a_{(M-z)}, b_1, \dots, b_z\}$ to $(\{a_1, \dots, a_{(M-z)}, b_1, \dots, b_z, b_{(z+1)}\} \setminus \{c\})$ must contain a link from a set $\mathcal{U}(i)$ with z alternatives from the set B to a set $\mathcal{U}(i+1)$ with $z+1$ alternatives from the set B . But with (8.3.9), we get that the link $\mathcal{U}(i) \rightarrow \mathcal{U}(i+1)$ must be a tie or a defeat.

With (2.1.5), we get that every path that contains only wins is stronger than every path that contains a tie or a defeat.

Therefore, every set $\{a_1, \dots, a_{(M-z)}, b_1, \dots, b_z\}$, that contains only z alternatives from the set B is disqualified by some set that contains $z+1$ alternatives from the set B .

Part 2: Part 1 is applied to $z := 0, \dots, (x-1)$. As indirect defeats are transitive (section 4.1), we get that every set with less than x alternatives from the set B is disqualified by some set with x alternatives from the set B . $\square$

The Smith criterion for multi-winner elections implies the Condorcet criterion for multi-winner elections. We get the Condorcet criterion for multi-winner elections when we restrict the Smith criterion for multi-winner elections to sets with exactly one alternative.

In example A53, the Smith criterion for multi-winner elections implies that at least one winner must come from the set $\{d, f\}$ because, whenever exactly one alternative from the set $\{d, f\}$ and exactly four alternatives from $A \setminus \{d, f\}$ are running, the alternative from $\{d, f\}$ is a winner of Schulze STV.

8.3.1: Example A

Suppose $M = 10$ and $x = 6$.

Then the Smith criterion for multi-winner elections has the following form:

Suppose all of the following conditions are satisfied:

$\emptyset \neq B \subsetneq A$ consists of at least $x = 6$ candidates.

($y = 1$): Whenever exactly $y = 1$ candidate of the set B and exactly $M + 1 - y = 10$ candidates of $A \setminus B$ are running, the candidate of the set B is in every potential winning set.

($y = 2$): Whenever exactly $y = 2$ candidate of the set B and exactly $M + 1 - y = 9$ candidates of $A \setminus B$ are running, the candidates of the set B are in every potential winning set.

($y = 3$): Whenever exactly $y = 3$ candidate of the set B and exactly $M + 1 - y = 8$ candidates of $A \setminus B$ are running, the candidates of the set B are in every potential winning set.

($y = 4$): Whenever exactly $y = 4$ candidate of the set B and exactly $M + 1 - y = 7$ candidates of $A \setminus B$ are running, the candidates of the set B are in every potential winning set.

($y = 5$): Whenever exactly $y = 5$ candidate of the set B and exactly $M + 1 - y = 6$ candidates of $A \setminus B$ are running, the candidates of the set B are in every potential winning set.

($y = 6$): Whenever exactly $y = 6$ candidate of the set B and exactly $M + 1 - y = 5$ candidates of $A \setminus B$ are running, the candidates of the set B are in every potential winning set.

Then when the used election method is applied on A , every potential winning set must contain at least $x = 6$ candidates of the set B .

Conditions ($y = 1$) to ($y = 5$) seem to be superfluous. Condition ($y = 6$) seems to be sufficient to guarantee that the set B should get at least $x = 6$ seats. However, example B (section 8.3.2) shows that, when we drop the conditions $y = 1, \dots, (x - 1)$, then the resulting criterion is not satisfiable anymore.

8.3.2: Example B

Suppose $M = 2$.

Then the Smith criterion for multi-winner elections has the following form:

Suppose

(a1) $\emptyset \neq B \subsetneq A$ consists of at least $x = 1$ candidate.

(a2) Whenever exactly one candidate of the set B and exactly two candidates of $A \setminus B$ are running, the candidate of the set B is in every potential winning set.

Then, when the used election method is applied on A , every potential winning set must contain at least $x = 1$ candidate of the set B .

Suppose

(b1) $\emptyset \neq B \subsetneq A$ consists of at least $x = 2$ candidates.

(b2) Whenever exactly one candidate of the set B and exactly two candidates of $A \setminus B$ are running, the candidate of the set B is in every potential winning set.

(b3) Whenever exactly two candidates of the set B and exactly one candidates of $A \setminus B$ are running, both candidates of the set B are in every potential winning set.

Then, when the used election method is applied on A , every potential winning set must contain at least $x = 2$ candidates of the set B .

Condition b2 seems to be superfluous. Conditions b1 and b3 seem to be sufficient to guarantee that the set B should get at least 2 seats. However, the following example shows that, when we drop condition b2, then there can be more than one set such that both winners must come from set B_1 and, simultaneously, both winners must come from set B_2 with $(B_1 \cap B_2) = \emptyset$. In the following example, we have $B_1 = \{a, b\}$ and $B_2 = \{c, d\}$.

The following example has been proposed by I.D. Hill (1995).

There are $N = 54$ voters and $C = 4$ alternatives for $M = 2$ seats:

	a	b	c	d
1	1	-	-	-
2	1	-	-	-
3	1	-	-	-
4	1	-	-	-

29	-	2	-	1
30	-	2	-	1
31	2	-	1	-
32	2	-	1	-
33	2	-	1	-
34	2	-	1	-
35	-	2	1	-
36	-	2	1	-
37	-	2	1	-
38	-	2	1	-
39	-	1	2	-
40	-	1	2	-
41	-	1	2	-
42	-	1	2	-
43	-	1	-	2
44	-	1	-	2
45	-	1	-	2
46	-	1	-	2
47	1	-	2	-
48	1	-	2	-
49	1	-	2	-
50	1	-	2	-
51	1	-	-	2
52	1	-	-	2
53	1	-	-	2
54	1	-	-	2

The links are:

	k	l	m	$N[\{l,m\};k]$	$N[\{k,m\};l]$	$N[\{k,l\};m]$
1	a	b	c	17.081633	17.081633	<u>19.836735</u>
2	a	b	d	17.081633	17.081633	<u>19.836735</u>
3	a	c	d	<u>19.125000</u>	17.437500	17.437500
4	b	c	d	<u>19.125000</u>	17.437500	17.437500

The corresponding digraph looks as follows:

When $\{a,b,c\}$ are running, the unique winning set is $\{a,b\}$.
 When $\{a,b,d\}$ are running, the unique winning set is $\{a,b\}$.
 When $\{a,c,d\}$ are running, the unique winning set is $\{c,d\}$.
 When $\{b,c,d\}$ are running, the unique winning set is $\{c,d\}$.

In the example above, alternatives a and b are winners whenever they and exactly one other alternative are running. Furthermore, alternatives c and d are winners whenever they and exactly one other alternative are running. The Smith criterion for multi-winner elections says that at least one alternative of the set $\{a,c\}$ must be elected, at least one alternative of the set $\{b,c\}$ must be elected, at least one alternative of the set $\{a,d\}$ must be elected, and at least one alternative of the set $\{b,d\}$ must be elected. So the Smith criterion for multi-winner elections says that either the set $\{a,b\}$ or the set $\{c,d\}$ must be the winner.

So this example shows that, for a set of M alternatives to be the unique winning set, it is not sufficient to win every contest between itself and some other set of M alternatives that differs in exactly one alternative.

In example B, Schulze STV chooses the set $\{a,b\}$.

8.4. Proportionality

Definition (Dummett-Droop Proportionality):

A preferential multi-winner election method satisfies *Dummett-Droop proportionality* (DDP) if the following holds for every $\emptyset \neq B \subsetneq A$ and for every $x \in \mathbb{N}$ with $x \leq \lfloor N / (M+1) \rfloor$:

Suppose that strictly more than $x \cdot N / (M+1)$ voters strictly prefer every alternative in B to every other alternative. In other words:

$$\left\| \{ v \in V \mid \forall a \in B \forall b \notin B: a \succ_v b \} \right\| > x \cdot N / (M+1).$$

Then at least x alternatives of set B must be elected.

It has been proposed by Droop (1881) that an alternative should be elected as soon as it has received more than $N / (M+1)$ votes. This idea has been generalized by Dummett to sets of alternatives (Dummett, 1984; Schulze, 2002). Today, DDP is considered a necessary and sufficient criterion for every preferential multi-winner election method to qualify as an STV method.

Claim:

Schulze STV, as defined in section 8.1, satisfies Dummett-Droop proportionality.

Proof (overview):

The proof is very similar to the proof that Schulze STV satisfies the Smith criterion for multi-winner elections (section 8.3). Therefore, we give only an overview.

Step 1: We prove that Schulze STV satisfies DDP when there are M seats and $C = M + 1$ alternatives. This step is trivial because, in the $C = M + 1$ case, we simply calculate $N[(\{a_1, \dots, a_{(M+1)}\} \setminus \{a_i\}); a_i]$ for every $i \in \{1, \dots, (M+1)\}$ and eliminate the alternative i with maximum $N[(\{a_1, \dots, a_{(M+1)}\} \setminus \{a_i\}); a_i]$.

Step 2: DDP leads to constraints of the form “ $abcdef(k)$ ”, saying that at least k alternatives of the set $\{a, b, c, d, e, f\}$ must be elected according to DDP. See the column “Dummett” in table 9.4.1.

Suppose $\mathcal{A} \in A_M$ violates DDP. Then there is a DDP constraint $abcdef(k)$, such that $\mathcal{A}$ contains only j alternatives of the set $\{a, b, c, d, e, f\}$ with $j < k$.

We then prove that there is a $\mathcal{B} \in A_M \setminus \{\mathcal{A}\}$ such that there is a path from $\mathcal{B}$ to $\mathcal{A}$ that contains only wins. We choose $\mathcal{B}$ as follows: We take an arbitrarily chosen alternative g from the set $\{a, b, c, d, e, f\}$ that is not in $\mathcal{A}$; we then apply Schulze STV to $(\mathcal{A} \cup \{g\})$; the resulting winning set is then the set $\mathcal{B}$; the link $\mathcal{B} \rightarrow \mathcal{A}$ is then a path from $\mathcal{B}$ to $\mathcal{A}$ that contains only wins.

Step 3: We prove that there cannot be a path from $\mathcal{A}$ to $\mathcal{B}$ that contains only wins because such a path would necessarily contain a link $\mathcal{C}(i) \rightarrow \mathcal{C}(i+1)$ where $\mathcal{C}(i)$ contains only j alternatives of the set $\{a, b, c, d, e, f\}$ and $\mathcal{C}(i+1)$

contains $j + 1$ alternatives of the set $\{a, b, c, d, e, f\}$. But as Schulze STV satisfies DDP in the $C = M + 1$ case, the link $\mathcal{C}(i) \rightarrow \mathcal{C}(i+1)$ must be a tie or a defeat.

As path defeats are transitive, there must be a $\mathfrak{X} \in A_M$ that is not disqualified by some other $\mathfrak{Y} \in A_M \setminus \{\mathfrak{X}\}$. As every $\mathfrak{A} \in A_M$ that violates DDP is disqualified by some other $\mathfrak{B} \in A_M \setminus \{\mathfrak{A}\}$, this $\mathfrak{X}$ must satisfy DDP. $\square$

9. Proportional Ranking

In party-list proportional representation, each party must submit a linear order of its candidates beforehand, without knowing how many seats it will win. Parties are often interested in ensuring that — no matter how many candidates are elected — the candidates elected should reflect the strengths of the different wings of the party as proportionally as possible (Otten, 1998, 2000; Rosenstiel, 1998; Warren, 1999; Skowron, 2017). A linear order with this property is called a *proportional ranking*. The two most important approaches to create a proportional ranking are the *bottom-up* approach (Rosenstiel, 1998) and the *top-down* approach (Otten, 1998, 2000).

The *bottom-up* approach says that we start with the situation where all C candidates are elected. Then, for $k = C$ to 2, we ask which candidate can be eliminated (without changing who is already eliminated) so that the distortion of the proportionality of the remaining candidates is as small as possible; the newly eliminated candidate then gets the k -th place of this party list.

The *top-down* approach says that we use a single-winner election method to fill the first place of this party list. Then, for $k = 2$ to C , we ask which candidate can be added to the already elected candidates (without changing who is already elected) so that the distortion of the proportionality is as small as possible; the newly added candidate then gets the k -th place of this party list.

I prefer the top-down approach to the bottom-up approach, because the bottom-up approach starts with the lowest and, therefore, (as the number of candidates is usually significantly larger than the number of seats this party can realistically hope to win) least important places so that slight fluctuations in the filling of the lowest places can have an enormous impact on the filling of the best places. Therefore, in this paper we presume that the top-down approach is being used.

In section 9.1, we will propose a new proportional ranking method. In sections 9.3 and 9.4, we will apply this method to the examples of Tideman’s database. The proposed proportional ranking method is based on the following idea:

- Suppose $a_1, \dots, a_{(k-1)} \in A$ are already elected.
- Suppose there are candidates $\emptyset \neq \{b_1, \dots, b_z\} \subseteq A \setminus \{a_1, \dots, a_{(k-1)}\}$ such that, whenever some candidate $b_j \in \{b_1, \dots, b_z\}$ is added to $\{a_1, \dots, a_{(k-1)}\}$, then choosing the set $\{a_1, \dots, a_{(k-1)}, b_j\}$ is compatible to the Smith criterion for k -winner elections (section 8.3).
- Then the k -th seat should go to one of the candidates in $\{b_1, \dots, b_z\}$.

9.1. Schulze Proportional Ranking

Proportional completion is defined in section 8.1.1. $N[\{a_1, \dots, a_k\}; g]$ is defined in section 8.1.2. $>_{D1}$ and $>_{D2}$ are two binary relations that each satisfy (2.1.1) – (2.1.3).

Stage 1:

We calculate a Schulze single-winner ranking $O_{final}(\sigma)$ on A , as defined in section 5.1, with $>_{D1}$.

Stage 2:

Proportional completion is used to complete V to W .

Stage 3:

For $k := 1$ to $(C-1)$ do

{
Suppose $a_1, \dots, a_{(k-1)}$ are already elected.

For each pair of alternatives $b, c \notin \{a_1, \dots, a_{(k-1)}\}$, we define:

$$H[b, c] := N[\{a_1, \dots, a_{(k-1)}, b\}; c].$$

We apply the Schulze single-winner election method, as defined in section 2.3.1 stage 2, on $H[i, j]$, instead of $N[i, j]$, and with $>_{D2}$. If there is only one potential winner, then it gets the k -th place. If there is more than one potential winner, then the k -th place goes to that potential winner b with $bc \in O_{final}(\sigma)$ for every other potential winner c .

}

9.2. Independence of Clones

In general, independence of clones means that, when some candidate $d \in A$ is replaced by a set of clones K as defined in (4.7.1) – (4.7.3), then this must neither help nor harm candidate d or any other candidate. In context of proportional ranking methods, this means that, when candidate d had the z -th place in the proportional ranking, then the highest ranked clone $g \in K$ must get the z -th place of the proportional ranking and there must be no change in the places 1, ..., $(z-1)$ of the proportional ranking.

The Schulze proportional ranking method satisfies independence of clones. To prove this, the proof in section 4.7 has to be applied to places 1, ..., z of the proportional ranking and to $H[x, y]$ instead of $N[x, y]$.

9.3. Example A53

The following series of tables illustrates the Schulze proportional ranking method when applied to example A53 of Tideman’s database with $>_{ratio}$ for $>_{D1}$ and $>_{margin}$ for $>_{D2}$. Pairwise wins are **fat and underlined**. Pairwise ties are *italic and underlined*.

$N[\{a,b,d,f,g,i,j,*\}]$	63.137255	61.285714	<u>63.996265</u>	--

The 7. place goes to alternative e .

	$N[\{a,b,d,e,f,g,j,*\};c]$	$N[\{a,b,d,e,f,g,j,*\};h]$	$N[\{a,b,d,e,f,g,j,*\};i]$
$N[\{a,b,c,d,e,f,g,j,*\}]$	--	<u>56.000000</u>	<u>55.750000</u>
$N[\{a,b,d,e,f,g,h,j,*\}]$	55.375000	--	55.750000
$N[\{a,b,d,e,f,g,i,j,*\}]$	55.375000	<u>56.000000</u>	--

The 8. place goes to alternative c .

	$N[\{a,b,c,d,e,f,g,j,*\};h]$	$N[\{a,b,c,d,e,f,g,j,*\};i]$
$N[\{a,b,c,d,e,f,g,h,j,*\}]$	--	49.555556
$N[\{a,b,c,d,e,f,g,i,j,*\}]$	<u>49.777778</u>	--

The 9. place goes to alternative i .

The 10. place goes to alternative h .

So, the Schulze proportional ranking is $j a g d f b e c i h$.

9.4. Tideman’s Database

In table 9.4.1, Schulze STV and Schulze proportional ranking are applied to the instances of Tideman’s (2000) database. We use $>_{ratio}$ for $>_{D1}$ and $>_{margin}$ for $>_{D2}$ because $>_{ratio}$ corresponds to proportional completion; the fact that we use $>_{ratio}$ for $>_{D1}$ means that it makes no difference whether we first calculate a Schulze single-winner ranking $O_{final}(\sigma)$ and then apply proportional completion or first apply proportional completion and then calculate a Schulze single-winner ranking $O_{final}(\sigma)$.

The column “name #1” contains the name of the instance. The column “name #2” contains the name of the same instance in Wichmann’s (1994) database. N is the number of voters. C is the number of alternatives. M is the number of seats.

Column “Dummett” contains the constraints given by “Dummett-Droop proportionality” (DDP), as defined in section 8.4. The constraints are separated by spaces. If this constraint consists of a single alternative, then this means that this alternative must be elected according to DDP. If this constraint has the form “ $abcdef(k)$ ” then this means that at least k alternatives of the set $\{a,b,c,d,e,f\}$ must be elected according to DDP. For example, in instance A35 the constraints are “ $f eijkq(1)$ ” so that (1) alternative f must be elected and (2) at least one alternative of the set $\{e,i,j,k,q\}$ must be elected according to DDP. In 3 instances (A64, A72, A83), there is only one set of M alternatives that can be elected according to DDP.

The column “Condorcet winners” contains the Condorcet winners in Schulze STV [according to (8.3.5)]; alternatives, that are only weak Condorcet winners [according to (8.3.6)], are listed in brackets (). The column “Condorcet losers” contains the Condorcet losers in Schulze STV [according to (8.3.7)]; alternatives, that are only weak Condorcet losers [according to (8.3.8)], are listed in brackets (). It is important to keep in mind that, as long as $>_{D2}$ satisfies (2.1.5), the Condorcet winners in Schulze STV, the Condorcet losers in Schulze STV, and the possible winning sets according to the Smith criterion (for multi-winner elections) in Schulze STV do not depend on the specific choice for $>_{D2}$. As long as $>_{D2}$ satisfies (2.1.4) and (2.1.5), the weak Condorcet winners in Schulze STV and the weak Condorcet losers in Schulze STV do not depend on the specific choice for $>_{D2}$.

The column “Schulze STV” contains the winning set of Schulze STV, as defined in section 8.1.3. When several sets are tied for winning, then (rather than listing all potential winning sets) the winning set chosen by the tie-breaker, as defined in section 8.1.3 stage 4, is listed. In 3 instances (A34, A88, A97), an alternative, that is a weak Condorcet winner, is not elected. In instances A34 and A97, this is due to the fact that the number of alternatives, that are weak Condorcet winners or non-weak Condorcet winners, is larger than the number of seats. In instance A34, the sets $\{a,b,c,d,e,f,g,h,j,k,m,n\}$, $\{a,b,c,d,e,f,g,h,j,k,l,m,n\}$, $\{a,b,c,d,e,g,h,j,k,l,m,n\}$, $\{a,b,c,e,f,g,h,j,k,l,m,n\}$, and $\{b,c,d,e,f,g,h,j,k,l,m,n\}$ are tied for winning; the tie-breaker chooses $\{a,b,c,d,e,f,g,h,j,k,l,m,n\}$, because (1) $da \in O_{final}(\sigma)$, $dl \in O_{final}(\sigma)$, $df \in O_{final}(\sigma)$, and $dg \in O_{final}(\sigma)$ so that the set $\{a,b,c,e,f,g,h,j,k,l,m,n\}$ is disqualified at the first stage for not containing alternative d , (2) $al \in O_{final}(\sigma)$, $af \in O_{final}(\sigma)$, and $ag \in O_{final}(\sigma)$ so that the set $\{b,c,d,e,f,g,h,j,k,l,m,n\}$ is disqualified at the second stage for not containing alternative a , (3) $lf \in O_{final}(\sigma)$ and $lg \in O_{final}(\sigma)$ so that the set $\{a,b,c,d,e,f,g,h,j,k,m,n\}$ is disqualified at the third stage for not containing alternative l , and (4) $fg \in O_{final}(\sigma)$ so that the set $\{a,b,c,d,e,g,h,j,k,l,m,n\}$ is disqualified at the fourth stage for not containing alternative f . In instance A88, the sets $\{a,c,e,f,g,h\}$, $\{b,c,e,f,g,h\}$, and $\{c,d,e,f,g,h\}$ are tied for winning; while only alternative d is a weak Condorcet winner, the tie-breaker chooses $\{a,c,e,f,g,h\}$, because $ab \in O_{final}(\sigma)$ and $ad \in O_{final}(\sigma)$. In instance A97, the sets $\{a,b\}$ and $\{a,c\}$ are tied for winning; the tie-breaker chooses $\{a,b\}$, because $bc \in O_{final}(\sigma)$.

The column “Schulze proportional ranking” contains the Schulze proportional ranking, as defined in section 9.1. When several rankings are tied for winning, then (rather than listing all potential rankings) the ranking chosen by the tie-breaker, as defined in section 9.1 stage 3 last sentence, is listed. In 5 instances (A04, A10, A12, A33, A67), the Schulze proportional ranking is not unique even with the proposed tie-breaker. This is due to the fact that, in these instances, even the Schulze single-winner ranking $O_{final}(\sigma)$ is not unique. Only in 6 of the 66 instances of Tideman’s database (A10, A11, A13, A33, A34, A59), the winning set of Schulze STV differs from the first M alternatives of Schulze proportional ranking.

The column “runtime” contains the runtime to calculate the Schulze STV winners. A Fujitsu RX 350S8 with two 6-core “E5-2630v2 @ 2.60 GHz” processors was used for the calculations. Hyper-threading was disabled. The programs to calculate the STV winners and the Schulze proportional ranking were written in Microsoft Visual C++ 2010.

Table 9.4.1 (part 3 of 3): Schulze STV applied to instances of Tideman’s database

In 45 instances (A01, A02, A05, A08, A10, A12, A14, A18, A19, A20, A23, A48, A49, A51, A52, A54, A56, A57, A63, A64, A66, A68, A69, A70, A71, A72, A73, A74, A76, A78, A79, A80, A81, A83, A84, A85, A86, A87, A89, A92, A93, A94, A96, A98, A99), there are M Condorcet winners [according to (8.3.5)].

In 16 instances, there are $M-1$ Condorcet winners. For the remaining seat, there is a set $\emptyset \neq B \subsetneq A$ such that the Smith criterion for multi-winner elections (section 8.3) says that every winning set must contain at least one alternative from the set B . Table 9.4.2 lists these instances and the set B .

	name #1	N	C	M	Condorcet winners	set B
1	A03	989	15	7	$b d e f h k$	$g n$
2	A04	43	14	2	i	$a f k$
3	A06	280	9	5	$c e h i$	$b f g$
4	A07	79	17	2	i	$c d$
5	A13	104	26	2	t	$i k$
6	A15	77	21	2	l	$a b c d g h i j$ $k m n p q r s t$
7	A17	867	13	8	$a b d e f j l$	$i m$
8	A22	44	11	2	k	$a b c d e g h i j$
9	A53	460	10	4	$a g j$	$d f$
10	A55	302	10	5	$a f i j$	$d e h$
11	A59	694	7	4	$d f g$	$b e$
12	A65	198	10	6	$b e f g j$	$a d$
13	A67	183	14	10	$b c e f g i j k l$	$h m n$
14	A88	135	9	6	$c e f g h$	$a b d$
15	A95	587	7	2	a	$b f$
16	A97	284	4	2	a	$b c$

Table 9.4.2: Instances of Tideman’s database with $M-1$ Condorcet winners

The 45 instances with M Condorcet winners are interesting because, in these instances, we know that we can remove all other alternatives or any subset of the other alternatives and the result will not change. This observation follows directly from the definition of Condorcet winners.

The 16 instances with $M-1$ Condorcet winners and a set B such that the last remaining winner must come from the set B are interesting because, again, we know that we can remove all other alternatives or any subset of the other alternatives and the result will not change. The proof for this is identical to the proof that the Schulze method satisfies Smith-IIA (section 4.8).

Only in 5 instances (A11, A33, A34, A35, A90), there are less than $M-1$ Condorcet winners. This shows that we succeeded in defining the Condorcet criterion for multi-winner elections in such a manner that there are always many Condorcet winners (section 8.3).

10. Mixed Member Proportional Representation

Today, many countries use *proportional representation by party lists* (PRPL). This election method has two serious problems. First, it gives too much power to the party machines that control the nomination processes. Second, it allows proportionality only according to one criterion: party affiliations.

A possible way to circumvent the shortcomings of PRPL is through *proportional representation by the single transferable vote* (STV). To cope with the large number of candidates who are typically running for a parliament, the electorate is divided into districts of e.g. 7 seats each and the same candidate must not run in more than one district. Droop proportionality is then satisfied only on the district level, so that it can happen that a party with about 10% of the votes does not win a single seat.

Therefore, people who promote STV in countries that use PRPL are frequently confronted with the defamation that they were dishonest and that their real aim was to increase the threshold for small parties to gain parliamentary representation from a *legal* threshold of typically about 5% in countries that are using PRPL to a *natural* threshold of typically about 10% in countries that are using STV. Because of this reason, it might be a useful strategy to include into the STV proposal a compensation of party proportionality on the national level.

One way to achieve this compensation of party proportionality is through *mixed member proportional representation* (MMP). Here, each voter gets two ballots: a *district ballot* and a *party ballot*. With the district ballots, the voters elect their district representatives. With the party ballots, the voters indicate their party support. When, on the national level, the elected district representatives do not reflect party proportionality (as indicated by the party ballots) in an appropriate manner, then *additional representatives* are added to the parliament to compensate party proportionality (so that the total size of the parliament increases). Usually, these additional representatives are chosen from candidate lists that have been submitted by the parties in advance of the elections. The main problem of this way to choose these additional representatives is that, again, it gives too much power to the party machines that control the nomination processes.

One way to avoid this problem of the common way to choose these additional representatives is to use MMP with the “*best loser*” method. Here, when a party gets additional representatives, then these additional representatives are those candidates who performed best in their respective districts without being elected. Advantage of the “best loser” method is that, with their district votes, the voters do not only elect their district representatives, they also decide (in those cases where a party gets additional representatives) who these additional representatives are.

Where concrete numbers are needed, we use the elections to the *Berlin House of Representatives* (“*Abgeordnetenhaus von Berlin*”) to illustrate the proposed method. The constitution of Berlin says that its House has a standard size of 130 seats; this is usually interpreted as saying that the House must have 130 seats plus eventual overhang seats plus eventual compensation seats. We recommend that 80% of these seats should be filled by STV on the district level.

10.1. The Districts

Berlin is currently divided into 12 boroughs (sing.: *Bezirk*, plur.: *Bezirke*).

	borough	eligible voters
1	Mitte	197,148
2	Friedrichshain-Kreuzberg	171,249
3	Pankow	283,368
4	Charlottenburg-Wilmersdorf	216,762
5	Spandau	162,922
6	Steglitz-Zehlendorf	217,191
7	Tempelhof-Schöneberg	232,529
8	Neukölln	200,578
9	Treptow-Köpenick	199,830
10	Marzahn-Hellersdorf	202,868
11	Lichtenberg	203,709
12	Reinickendorf	181,562
	total:	2,425,480

Table 10.1.1: The 12 Berlin boroughs

(Source: Amt für Statistik Berlin-Brandenburg, “Statistischer Bericht B VII 2-1 – 5j / 16: Wahlen zum Abgeordnetenhaus von Berlin und zu den Bezirksverordnetenversammlungen 2016 — Vorwahldaten, Strukturdaten”, Potsdam, Germany, 2016, page 7 https://www.wahlen-berlin.de/Wahlen/Be2016/SB_B07-02-01_2016j05_BE.pdf)

Graphic 10.1.2: The 12 Berlin boroughs

(Source: Von Nodder - Based on Water map of Berlin, CC BY-SA 3.0, <https://commons.wikimedia.org/w/index.php?curid=4332728>)

We recommend that the districts for the elections to the House should be the 12 Berlin boroughs. In the Hill-Huntington method, each district first gets one seat; then the numbers of eligible voters for each district are divided by $\sqrt{1 \cdot 2}$, $\sqrt{2 \cdot 3}$, $\sqrt{3 \cdot 4}$, ... and the remaining seats go to the largest quotients. When the Hill-Huntington method is being used to allocate the 104 district seats to the 12 districts, then we get two 7-seat districts (Friedrichshain-Kreuzberg, Spandau), four 8-seat districts (Mitte, Neukölln, Treptow-Köpenick, Reinickendorf), four 9-seat districts (Charlottenburg-Wilmersdorf, Steglitz-Zehlendorf, Marzahn-Hellersdorf, Lichtenberg), one 10-seat district (Tempelhof-Schöneberg), and one 12-seat district (Pankow) [seats 1–104 in table 10.1.3]. The compensation seats go to Mitte (2 seats), Friedrichshain-Kreuzberg (2 seats), Pankow (3 seats), Charlottenburg-Wilmersdorf (2 seats), Spandau (2 seats), Steglitz-Zehlendorf (2 seats), Tempelhof-Schöneberg (2 seats), Neukölln (3 seats), Treptow-Köpenick (2 seats), Marzahn-Hellersdorf (2 seats), Lichtenberg (2 seats), and Reinickendorf (2 seats) [seats 105–130 in table 10.1.3]. If additional 15 compensation seats should be needed to achieve proportionality, then these seats go to Mitte (one seat), Friedrichshain-Kreuzberg (one seat), Pankow (one seat), Charlottenburg-Wilmersdorf (2 seats), Steglitz-Zehlendorf (2 seats), Tempelhof-Schöneberg (2 seats), Neukölln (one seat), Treptow-Köpenick (2 seats), Marzahn-Hellersdorf (one seat), Lichtenberg (one seat), and Reinickendorf (one seat) [seats 131–145 in table 10.1.3]. This guarantees that, regardless of the final number of seats, each district gets its proportional share of seats.

district	eligible voters	number of eligible voters divided by ...															
		... $\sqrt{(1 \cdot 2)}$	... $\sqrt{(2 \cdot 3)}$	... $\sqrt{(3 \cdot 4)}$	... $\sqrt{(4 \cdot 5)}$	... $\sqrt{(5 \cdot 6)}$	... $\sqrt{(6 \cdot 7)}$	... $\sqrt{(7 \cdot 8)}$	... $\sqrt{(8 \cdot 9)}$	... $\sqrt{(9 \cdot 10)}$	... $\sqrt{(10 \cdot 11)}$	... $\sqrt{(11 \cdot 12)}$	... $\sqrt{(12 \cdot 13)}$	... $\sqrt{(13 \cdot 14)}$	... $\sqrt{(14 \cdot 15)}$	... $\sqrt{(15 \cdot 16)}$	... $\sqrt{(16 \cdot 17)}$
Mitte	197,148	139,405 (21. seat)	80,485 (34. seat)	56,912 (46. seat)	44,084 (58. seat)	35,994 (71. seat)	30,421 (83. seat)	26,345 (96. seat)	23,234 (107. seat)	20,781 (120. seat)	18,797 (134. seat)	17,160	15,784	14,614	13,605	12,726	11,954

Charlottenburg-Wilmersdorf	216,762	153,274 (16. seat)	88,493 (28. seat)	62,574 (41. seat)	48,469 (52. seat)	39,575 (63. seat)	33,447 (74. seat)	28,966 (87. seat)	25,546 (98. seat)	22,849 (110. seat)	20,667 (122. seat)	18,867 (133. seat)	17,355 (143. seat)	16,067	14,958	13,992	13,143
Spandau	162,922	115,203 (25. seat)	66,513 (38. seat)	47,032 (53. seat)	36,430 (70. seat)	29,745 (85. seat)	25,139 (99. seat)	21,771 (113. seat)	19,201 (128. seat)	17,173	15,534	14,181	13,044	12,077	11,243	10,517	9,879
Steglitz-Zehlendorf	217,191	153,577 (15. seat)	88,668 (27. seat)	62,698 (40. seat)	48,565 (51. seat)	39,653 (62. seat)	33,513 (73. seat)	29,023 (86. seat)	25,596 (97. seat)	22,894 (108. seat)	20,708 (121. seat)	18,904 (132. seat)	17,389 (142. seat)	16,099	14,988	14,020	13,169
Tempelhof-Schöneberg	232,529	164,423 (14. seat)	94,930 (26. seat)	67,125 (37. seat)	51,995 (48. seat)	42,454 (60. seat)	35,880 (72. seat)	31,073 (80. seat)	27,404 (89. seat)	24,511 (101. seat)	22,171 (112. seat)	20,239 (123. seat)	18,617 (135. seat)	17,236 (145. seat)	16,046	15,010	14,099
Neukölln	200,578	141,830 (19. seat)	81,886 (31. seat)	57,902 (44. seat)	44,851 (56. seat)	36,620 (68. seat)	30,950 (81. seat)	26,803 (93. seat)	23,638 (105. seat)	21,143 (117. seat)	19,124 (130. seat)	17,458 (140. seat)	16,059	14,868	13,841	12,947	12,162
Treptow-Köpenick	199,830	141,301 (20. seat)	81,580 (33. seat)	57,686 (45. seat)	44,683 (57. seat)	36,484 (69. seat)	30,834 (82. seat)	26,703 (94. seat)	23,550 (106. seat)	21,064 (118. seat)	19,053 (131. seat)	17,393 (141. seat)	15,999	14,812	13,790	12,899	12,116
Marzahn-Hellersdorf	202,868	143,449 (18. seat)	82,821 (30. seat)	58,563 (43. seat)	45,363 (55. seat)	37,038 (67. seat)	31,303 (78. seat)	27,109 (91. seat)	23,908 (104. seat)	21,384 (116. seat)	19,343 (127. seat)	17,657 (139. seat)	16,242	15,038	13,999	13,095	12,301
Lichtenberg	203,709	144,044 (17. seat)	83,164 (29. seat)	58,806 (42. seat)	45,551 (54. seat)	37,192 (66. seat)	31,433 (77. seat)	27,222 (90. seat)	24,007 (103. seat)	21,473 (114. seat)	19,423 (126. seat)	17,731 (138. seat)	16,310	15,100	14,057	13,149	12,352
Reinickendorf	181,562	128,384 (22. seat)	74,122 (35. seat)	52,412 (47. seat)	40,598 (61. seat)	33,149 (76. seat)	28,016 (88. seat)	24,262 (102. seat)	21,397 (115. seat)	19,138 (129. seat)	17,311 (144. seat)	15,803	14,537	13,458	12,529	11,720	11,009

Table 10.1.3: Allocation of the seats to the 12 districts according to the Hill-Huntington method

10.2. The District Ballot

The same candidate must not run in more than one district. The same candidate must not run simultaneously as an independent candidate and as a party candidate. The same candidate must not run for more than one party simultaneously.

On the district ballot, the candidates are sorted according to their party affiliations. Candidates with the same party affiliation are sorted in an order determined by this party. Each party can nominate as many candidates as it wants to.

The individual voter ranks the candidates in order of preference. The individual voter may ...

... give the same preference to more than one candidate.

... keep candidates unranked. When a given voter does not rank all candidates, then this means (1) that this voter strictly prefers all ranked candidates to all not ranked candidates and (2) that this voter is indifferent between all not ranked candidates.

... skip preferences. However, skipping some preferences does not have any impact on the result of the elections, since the result of the elections depends only on the order in which the individual voter ranks the candidates and not on the absolute preferences of the individual voters.

... give preferences to party labels. When a voter gives a preference to a party label, then this means that each candidate of this party gets this preference unless this voter explicitly gives a different preference to this candidate.

Graphic 10.2.1 shows how a cast district ballot could look like. Graphic 10.2.2 illustrates how this district ballot would be interpreted.

The winners of the district seats are calculated by Schulze STV (section 8).

Elections to the Berlin House of Representatives on 17. September 2006

Graphic 10.2.2: Interpretation of the cast district ballot

10.3. The Party Ballot

On the party ballot of a given district, all those parties are listed that have nominated district candidates. The individual voter can vote for one and only one party. Graphic 10.3.1 shows how a party ballot for district Friedrichshain-Kreuzberg could look like.

The district ballot and the party ballot are on the same sheet of paper. This is necessary because the weight of a voter’s party vote can depend on this voter’s district vote.

Elections to the Berlin House of Representatives on 17. September 2006 Party Ballot for district Friedrichshain-Kreuzberg <i>please vote for one and only one party</i> 	
01: Social Democratic Party of Germany (SPD)	
02: Christian Democratic Union of Germany (CDU)	
03: Left Party	
04: Alliance '90 / The Greens (B'90G)	
05: Free Democratic Party of Germany (FDP)	
06: The Republicans (REP)	
07: Ecological Democratic Party (ödp)	
08: Civil Rights Movement Solidarity (BüSo)	
09: Humane Economy Party

10.4. Allocation of District Voters to District Winners

For each district, we calculate an allocation of the voters of this district to the district winners of this district. The purpose of this allocation will be explained in section 10.5.

Table 10.4.1 shows the voting patterns in example A53 before and after proportional completion (restricted to the district winners).

before proportional completion						voters	after proportional completion					
voting pattern	number of voters	<i>a</i>	<i>d</i>	<i>g</i>	<i>j</i>		number of voters	<i>a</i>	<i>d</i>	<i>g</i>	<i>j</i>	voting pattern
1	8	1	3	2	3	1, 41, 230, 238, 402, 440, 443, 451	2.556098	1	3	2	4	1.001

	460						460.000000					

Table 10.4.1 (part 3 of 3): the voting patterns in example A53

To calculate the allocation of the voters to the winners, we proceed as follows:

Step #1: Suppose a_m is the number of voters with voting profile m . For example, line 16 of table 10.4.2 says that, after proportional completion, $a_m = 20.476919$ voters have the voting pattern $j > d > a > g$.

Suppose x_{mn} is the share of voter m that is allocated to candidate n . Then we must have

$$(10.4.1) \quad \sum_{m=1}^{24} (a_m \cdot x_{mn}) = 115 \quad \text{for every candidate } n.$$

$$(10.4.2) \quad \sum_{n=1}^4 x_{mn} = 1 \quad \text{for every voter } m.$$

$$(10.4.3) \quad x_{mn} \geq 0 \quad \text{for every voter } m \text{ and every candidate } n.$$

We minimize [subject to (10.4.1) – (10.4.3)] $\max \{ x_{mr} \}$ where candidate r is the fourth preference of voter m . We then fix the x_{mr} with maximum x_{mr} . We then minimize [subject to (10.4.1) – (10.4.3) and subject to those x_{mr} that have already been fixed] $\max \{ x_{mr} \}$ (again where candidate r is the fourth preference of voter m) for the remaining voters. We proceed until x_{mr} is fixed wherever candidate r is the fourth preference of voter m .

For example A53, we get $x_{mr} = 0$ wherever candidate r is the fourth preference of voter m . So a voter is never allocated to his fourth preference.

Step #2: We minimize [subject to (10.4.1) – (10.4.3) and subject to those x_{mr} that have been fixed in Step #1] $\max \{ x_{mr} + x_{ms} \}$ where candidate r is the fourth preference and candidate s is the third preference of voter m . We fix the x_{ms} with maximum $x_{mr} + x_{ms}$. We then minimize [subject to (10.4.1) – (10.4.3) and subject to those x_{mr} and x_{ms} that have already been fixed] $\max \{ x_{mr} + x_{ms} \}$ for the remaining voters. We proceed until x_{ms} is fixed wherever candidate s is the third preference of voter m .

For example A53, we get $x_{ms} = 0$ wherever candidate s is the third preference of voter m . So a voter is never allocated to his third preference.

Step #3: We minimize [subject to (10.4.1) – (10.4.3) and subject to those x_{mr} and x_{ms} that have been fixed in Step #1 and Step #2] $\max \{ x_{mr} + x_{ms} + x_{mt} \}$ where candidate r is the fourth preference, candidate s is the third preference, and candidate t is the second preference of voter m . We fix the x_{mt} with maximum $x_{mr} + x_{ms} + x_{mt}$. We then minimize [subject to (10.4.1) – (10.4.3) and subject to those x_{mr} , x_{ms} , and x_{mt} that have already been fixed] $\max \{ x_{mr} + x_{ms} + x_{mt} \}$ for the remaining voters. We proceed until x_{mt} is fixed wherever candidate t is the second preference of voter m .

For example A53, we get $\max \{ x_{mr} + x_{ms} + x_{mt} \} = 0.583579$ where candidate r is the fourth preference, candidate s is the third preference, and candidate t is the second preference of voter m . So 58% of these votes are allocated to this voter’s fourth, third or second preference. See the profiles #1, #2, #15, #16, #21, and #22 in table 10.4.2. We fix $x_{mr} + x_{ms} + x_{mt}$ for these voters.

Next, we minimize [subject to (10.4.1) – (10.4.3) and subject to those x_{mr} , x_{ms} and x_{mt} that have already been fixed] $\max \{ x_{mr} + x_{ms} + x_{mt} \}$ for the remaining voters. We get $\max \{ x_{mr} + x_{ms} + x_{mt} \} = 0.279045$ where candidate r is the fourth preference, candidate s is the third preference, and candidate t is the second preference of voter m . So 28% of these votes are allocated to this voter’s fourth, third or second preference. See the profiles #10, #12, #18, and #24 in table 10.4.2. We now fix $x_{mr} + x_{ms} + x_{mt}$ also for these voters.

Next, we minimize [subject to (10.4.1) – (10.4.3) and subject to those x_{mr} , x_{ms} and x_{mt} that have already been fixed] $\max \{ x_{mr} + x_{ms} + x_{mt} \}$ for the remaining voters. We get $\max \{ x_{mr} + x_{ms} + x_{mt} \} = 0.250164$ where candidate r is the fourth preference, candidate s is the third preference, and candidate t is the second preference of voter m . So 25% of these votes are allocated to this voter’s fourth, third or second preference. See the profiles #3 and #5 in table 10.4.2. We now fix $x_{mr} + x_{ms} + x_{mt}$ also for these voters.

Next, we minimize [subject to (10.4.1) – (10.4.3) and subject to those x_{mr} , x_{ms} and x_{mt} that have already been fixed] $\max \{ x_{mr} + x_{ms} + x_{mt} \}$ for the remaining voters. We get $\max \{ x_{mr} + x_{ms} + x_{mt} \} = 0.000000$ where candidate r is the fourth preference, candidate s is the third preference, and candidate t is the second preference of voter m . So 0% of these votes are allocated to this voter’s fourth, third or second preference. See the profiles #4, #6, #7, #8, #9, #11, #13, #14, #17, #19, #20, and #23 in table 10.4.2.

The above allocation procedure is motivated by the fact that the winners of an STV election are spaced roughly at equal distance.

	number of voters					share				votes			
		a	d	g	j	a	d	g	j	a	d	g	j

Table 10.4.2: Allocation of the voters to the district winners in example A53

In the general case with M seats, N voters, and W different voting profiles after proportional completion, we have:

$$(10.4.4) \quad \sum_{m=1}^W (a_m \cdot x_{mn}) = N / M \quad \text{for every candidate } n.$$

$$(10.4.5) \quad \sum_{n=1}^M x_{mn} = 1 \quad \text{for every voting profile } m.$$

$$(10.4.6) \quad x_{mn} \geq 0 \quad \text{for every voting profile } m \text{ and every candidate } n.$$

x_{mn} is the share of voting profile m that is allocated to candidate n .
 a_m is the number of voters in voting profile m .

For $i := M$ to 2, we proceed as follows:

Subject to (10.4.4) – (10.4.6) and subject to those x_{mn} that have already been fixed, we minimize

$$\max \left\{ \sum_{r=i}^M x_{m, R_m(r)} \mid m \in \{1, \dots, W\} \text{ with } x_{m, R_m(i)} \text{ has not yet been fixed} \right\}$$

where $R_m(r)$ is the candidate with the r -th preference in voting profile m . We fix $x_{m, R_m(i)}$ with maximum $\sum_{r=i}^M x_{m, R_m(r)}$. We proceed until $x_{m, R_m(i)}$ is fixed for all $m \in \{1, \dots, W\}$.

For example, row 7 of table 10.4.1 says that, before proportional completion, there are 10 voters (voters #9, #51, #231, #272, #327, #371, #382, #412, #414, #417) who ranked the candidates $a > d \approx g \approx j$. These voters are replaced by 0.805282 voters who rank the candidates $a > d > g > j$ (row 7.001), 1.185668 voters who rank the candidates $a > d > j > g$ (row 7.002), 1.204172 voters who rank the candidates $a > g > d > j$ (row 7.003), 2.294764 voters who rank the candidates $a > j > d > g$ (row 7.004), 1.985874 voters who rank the candidates $a > g > j > d$ (row 7.005), and 2.524240 voters who rank the candidates $a > j > g > d$ (row 7.006) after proportional completion.

before proportional completion						voters	after proportional completion					
voting pattern	number of voters	a	d	g	j		number of voters	a	d	g	j	voting pattern
7	10	1	2	2	2	9, 51, 231, 272, 327, 371, 382, 412, 414, 417	0.805282	1	2	3	4	7.001
							1.185668	1	2	4	3	7.002
							1.204172	1	3	2	4	7.003
							2.294764	1	3	4	2	7.004
							1.985874	1	4	2	3	7.005
							2.524240	1	4	3	2	7.006

Row 7 of table 10.4.1

Row 1 of table 10.4.2 says that, from every voter who votes $a > d > g > j$, 0.416421 is allocated to candidate a and 0.583579 is allocated to candidate d . Row 2 of table 10.4.2 says that, from every voter who votes $a > d > j > g$, 0.416421 is allocated to candidate a and 0.583579 is allocated to candidate d . Row 3 of table 10.4.2 says that, from every voter who votes $a > g > d > j$, 0.749836 is allocated to candidate a and 0.250164 is allocated to candidate g . Row 4 of table 10.4.2 says that, from every voter who votes $a > j > d > g$, 1.000000 is allocated to candidate a . Row 5 of table 10.4.2 says that, from every voter who votes $a > g > j > d$, 0.749836 is allocated to candidate a and 0.250164 is allocated to candidate g . Row 6 of table 10.4.2 says that, from every voter who votes $a > j > g > d$, 1.000000 is allocated to candidate a .

	number of voters					share				votes			
		a	d	g	j	a	d	g	j	a	d	g	j
1	10.994148	1	2	3	4	0.416421	0.583579			4.578195	6.415952		
2	20.545315	1	2	4	3	0.416421	0.583579			8.555500	11.989811		
3	15.021513	1	3	2	4	0.749836		0.250164		11.263672		3.757842	
4	25.451689	1	3	4	2	1.000000				25.451688			
5	20.791365	1	4	2	3	0.749836		0.250164		15.590114		5.201251	
6	23.213671	1	4	3	2	1.000000				23.213670			

Rows 1–6 of table 10.4.2

When we combine table 10.4.1 and table 10.4.2, we get that, from every voter who votes $a > d \approx g \approx j$, a share of $(0.805282 / 10) \cdot 0.416421 + (1.185668 / 10) \cdot 0.416421 + (1.204172 / 10) \cdot 0.749836 + (2.294764 / 10) \cdot 1.000000 + (1.985874 / 10) \cdot 0.749836 + (2.524240 / 10) \cdot 1.000000 = 0.804009$ is allocated to candidate a , a share of $(0.805282 / 10) \cdot 0.583579 + (1.185668 / 10) \cdot 0.583579 = 0.116188$ is allocated to candidate d , and a share of $(1.204172 / 10) \cdot 0.250164 + (1.985874 / 10) \cdot 0.250164 = 0.079804$ is allocated to candidate g . In other words: A vote $a > d \approx g \approx j$ contributes with 80% to the election of candidate a , with 12% to the election of candidate d , and with 8% to the election of candidate g .

	number of voters					share				votes

Table 10.4.3: Allocation of the voters to the district winners in example A53

Table 10.4.3 summarizes tables 10.4.1 and 10.4.2. Table 10.4.3 lists, for every voter of table 10.4.1, how he is allocated to the winners in example A53.

10.5. Allocation of Seats to Parties

We use the Sainte-Laguë method to determine how many seats each party gets. We use 0.8 as first divisor because, as 80% of the seats are district seats, an independent candidate needs 80% of a quota to get elected. So we take the party votes of each party and divide them by 0.8, 1.5, 2.5, 3.5, ... and the 130 seats of the House go to the 130 largest quotients.

Now it can happen that a party a has already won more district seats than it deserves according to its proportional share of party votes (*overhang seats*). In this case, we increase the number of party votes of party a by adding some of those voters, whose district vote has been allocated in section 10.4 to a candidate of party a , to party a .

To use a more formal language: Suppose $0 \leq T(x) \leq 1$ is the share of each voter whose ballot vote has been allocated to a candidate of party x and whose party vote will be allocated to party x (regardless to which party this voter has actually given his party vote). Then we start with $T(x) = 0$ for each party x . When some party a has won overhang seats, then we increase $T(a)$ until party a has enough party votes so that it has no overhang anymore; increasing $T(a)$ means that the share $T(a)$ of each voter, whose district vote has been allocated to a candidate of party a , is automatically interpreted as a party vote for party a and $1 - T(a)$ of each voter, whose district vote has been allocated to a candidate of party a , is interpreted as a party vote for that party for which this voter has actually voted with his party ballot (section 10.3), which might also be party a . If e.g. a voter contributed with 0.804009 to the election of district winners of party a with his district vote (according to section 10.4) and gave his party vote to party b , then $0.804009 \cdot T(a)$ of this voter's party vote goes to party a . When we increase $T(a)$, it can happen that we create an overhang for some other party b ; in this case, we also have to increase $T(b)$. Increasing $T(b)$ however can, again, lead to an overhang for party a . So we have to apply this procedure several times until either (i) it converges to a distribution of party votes without an overhang for any party or (ii) $T(x) = 1$ for some party x . In the latter case, the total number of seats is increased by 1 and the calculation of $T(x)$ is restarted.

Independent candidates are treated as parties with no initial party votes.

Basic idea behind this procedure is the idea that, when party a has an uncompensated overhang, then those voters, who contributed to the election of some candidate of party a with their district vote and who voted for some other party b with their party vote, would have a double voting power. Therefore, a share $0 \leq T(a) \leq 1$ of these votes should be counted for party a and not for party b . This share $T(a)$ should be chosen just large enough that this double voting power disappears.

10.6. Allocation of the Party Seats to its District Organizations

Suppose a_i is the number of party votes (including those voters who have been allocated to party a by raising $T(a)$ and excluding those voters who have been allocated to some other party b by raising $T(b)$ in section 10.5) for party a in district i . Suppose $s_i(a)$ is the number of district seats that the party a has won in district i (according to section 10.2).

To allocate the seats of party a to its district organizations, first each district organization gets $s_i(a)$ seats. We then divide the numbers of party votes for party a in each district i by $(s_i(a) + 0.5)$, $(s_i(a) + 1.5)$, $(s_i(a) + 2.5)$, $(s_i(a) + 3.5)$, ... The remaining seats go to the largest quotients.

Now it can happen that the total number of seats for a district differs from the number of seats this district must get according to table 10.1.3. In this case, we apply Pukelsheim's biproportional method (Pukelsheim, 2004).

To use a more formal language: For each district i , we calculate a factor F_i . This factor depends only on the district i and is the same for all parties. The factor F_i is chosen in such a manner that, when each party a applies the Sainte-Laguë method to $a_i \cdot F_i$ (instead of a_i), then each district gets exactly as many seats as it should get according to table 10.1.3.

10.7. Best Losers

When a district organization of party a has won more seats (according to section 10.6) than it has won district seats (according to section 10.2), then these additional seats go to the “best losers” of this party. To determine these best losers, we apply Schulze STV, but we restrict it to those voters who voted for party a with their party vote (including those voters who have been allocated to party a by raising $T(a)$ and excluding those voters who have been allocated to some other party b by raising $T(b)$ in section 10.5) and those candidates who have been nominated by party a (according to section 10.2).

For example, if the candidates c_1 and c_2 are those candidates who have run for candidate a on the district ballot and have won district seats and if the district organization has won additional 2 seats according to section 10.6, then the final winners for party a are the candidates (c_1, c_2, c_m, c_n) with $P_{D2}[(c_1, c_2, c_m, c_n), (c_1, c_2, c_r, c_s)] \gtrsim_{D2} P_{D2}[(c_1, c_2, c_r, c_s), (c_1, c_2, c_m, c_n)]$ for every other set of candidates (c_1, c_2, c_r, c_s) according to (8.1.3.1).

When the list of candidates of a district organization gets exhausted, then the remaining seats stay vacant.

10.8. Vacant Seats

(1) Suppose a seat, that has been won by the district vote (according to section 10.2), gets vacant. Then this seat is filled by recounting the district ballots. Those candidates who have died or who have won a compensation seat (according to section 10.7) are ignored. So when $(c_1, \dots, c_n)$ are the current winners. Then the vacant seat goes to candidate $c_i \notin \{c_1, \dots, c_n\}$ with $P_{D2}[(c_1, \dots, c_n, c_i), (c_1, \dots, c_n, c_j)] \gtrsim_{D2} P_{D2}[(c_1, \dots, c_n, c_j), (c_1, \dots, c_n, c_i)]$ for every other candidate $c_j \notin \{c_1, \dots, c_n\}$ according to (8.1.3.1).

(2) Suppose a compensation seat (according to section 10.7) gets vacant. Then this seat is filled by recounting the district ballots. Suppose this seat went to party a . Then the recount is restricted to those voters who voted for party a with their party vote (including those voters who have been allocated to party a by raising $T(a)$ and excluding those voters who have been allocated to some other party b by raising $T(b)$ in section 10.5) and those candidates who have been nominated by party a (according to section 10.2). Those candidates who have died are ignored. So when $(c_1, \dots, c_n)$ are those candidates of party a who are currently holding a district seat (according to section 10.2) or a compensation seat (according to section 10.7). Then the vacant seat goes to candidate $c_i \notin \{c_1, \dots, c_n\}$ with $P_{D2}[(c_1, \dots, c_n, c_i), (c_1, \dots, c_n, c_j)] \gtrsim_{D2} P_{D2}[(c_1, \dots, c_n, c_j), (c_1, \dots, c_n, c_i)]$ for every other candidate $c_j \notin \{c_1, \dots, c_n\}$ according to (8.1.3.1).

11. Comparison with other Methods

Table 11.2 compares the Schulze method (with margins) with its main contenders. Extensive descriptions of the different methods can be found in publications by Fishburn (1977), Nurmi (1987), Kopfermann (1991), Levin and Nalebuff (1995), and Tideman (2006). As most of these methods only generate a set $\mathcal{S}$ of potential winners and don’t generate a binary relation $\mathcal{O}$, only that part of the different criteria is considered that refers to the set $\mathcal{S}$ of potential winners.

In terms of satisfied and violated criteria, that election method, that comes closest to the Schulze method, is Tideman’s ranked pairs method (Tideman, 1987). The only difference is that the ranked pairs method doesn’t choose from the MinMax set $\mathcal{B}_D$.

The ranked pairs method works from the strongest to the weakest link. The link xy is locked if and only if it doesn’t create a directed cycle with already locked links. Otherwise, this link is locked in its opposite direction.

In example 1 (section 3.1), the ranked pairs method locks db . Then it locks cb . Then it locks ac . Then it locks ab , since locking ba in its original direction would create a directed cycle with the already locked links ac and cb . Then it locks cd . Then it locks ad , since locking da in its original direction would create a directed cycle with the already locked links ac and cd .

The winner of the ranked pairs method is alternative $a \notin \mathcal{B}_D = \{d\}$, because there is no locked link that ends in alternative a .

Although Tideman’s ranked pairs method is that election method that comes closest to the Schulze method in terms of satisfied and violated criteria, random simulations by Wright (2009) showed that that election method, that agrees the most frequently with the Schulze method, is the Simpson-Kramer MinMax method (table 11.1). This observation has been confirmed by Petry (2000), Heitzig (2004a), Darlington (2018, 2023), and Pacuit (2021). See also table 11.3.

Table 11.2: Comparison of Election Methods

"Y" = compliance

"N" = violation

In the introduction of this paper, I mentioned that the purpose of the Schulze method is to create an election method that satisfies the Smith criterion, reversal symmetry and independence of clones and that agrees with the Simpson-Kramer MinMax method whenever possible. To check whether the Schulze method delivers, we will compare the Schulze method with two other methods that satisfy the Smith criterion, reversal symmetry and independence of clones: Tideman’s ranked pairs method (Tideman, 1987) and Heitzig’s river method (Döring, 2025).

Example 14 (section 3.14) demonstrates the difference between the Simpson-Kramer MinMax method, the Schulze method, Tideman’s ranked pairs method and Heitzig’s river method. The winner of the Schulze method in example 14 is alternative b .

Simpson-Kramer MinMax method: This method calculates, for every alternative $x \in A$, the strongest link from some other alternative $y \in A \setminus \{x\}$ to alternative x . The winner is that alternative $x \in A$ for which

$$\max_D \{ (N[y,x], N[x,y]) \mid y \in A \setminus \{x\} \}$$

is the weakest. In example 14, we have :

$$\begin{aligned} \max_D \{ (N[y,a], N[a,y]) \mid y \in A \setminus \{a\} \} &\approx_D (62,35). \\ \max_D \{ (N[y,b], N[b,y]) \mid y \in A \setminus \{b\} \} &\approx_D (57,40). \\ \max_D \{ (N[y,c], N[c,y]) \mid y \in A \setminus \{c\} \} &\approx_D (56,41). \\ \max_D \{ (N[y,d], N[d,y]) \mid y \in A \setminus \{d\} \} &\approx_D (58,39). \\ \max_D \{ (N[y,e], N[e,y]) \mid y \in A \setminus \{e\} \} &\approx_D (63,34). \\ \max_D \{ (N[y,f], N[f,y]) \mid y \in A \setminus \{f\} \} &\approx_D (59,38). \end{aligned}$$

So the winner of the Simpson-Kramer MinMax method in example 14 is alternative c .

Tideman’s ranked pairs method: From the strongest to the weakest link, we proceed as follows: When locking this link doesn’t create a directed cycle with already locked links, then we lock this link in its original direction. When locking this link creates a directed cycle with already locked links, then we lock this link in its opposite direction.

In example 14, we lock $d \rightarrow e$ with a strength of (63,34). We then lock $f \rightarrow a$ with a strength of (62,35). We then lock $a \rightarrow e$ with a strength of (61,36). We then lock $b \rightarrow e$ with a strength of (60,37). We then lock $f \rightarrow e$ with a strength of (59,38), since locking ef in its original direction would create a directed cycle with the already locked links $f \rightarrow a$ and $a \rightarrow e$. We then lock $f \rightarrow d$ with a strength of (58,39). We then lock $d \rightarrow b$ with a strength of (57,40). We then lock $b \rightarrow c$ with a strength of (56,41). We then lock $e \rightarrow c$ with a strength of (55,42). We then lock $d \rightarrow a$ with a strength of (54,43). We then lock $a \rightarrow c$ with a strength of (53,44), since locking ca in its original direction would create a directed cycle with the already locked links $a \rightarrow e$ and $e \rightarrow c$. We then lock $a \rightarrow b$ with a strength of (52,45). We then lock $d \rightarrow c$ with a strength of (51,46), since locking cd in its original direction would create a directed cycle with the already locked links $d \rightarrow b$ and $b \rightarrow c$. We then lock $f \rightarrow b$ with a strength of (50,47). We then lock $f \rightarrow c$ with a strength of (49,48), since locking cf in its original direction would create a directed cycle with the already locked links $f \rightarrow a$, $a \rightarrow e$ and $e \rightarrow c$.

The winner of Tideman’s ranked pairs method is alternative f because $f \rightarrow y$ for every other alternative $y \in A \setminus \{f\}$.

Heitzig’s river method: From the strongest to the weakest link, we proceed as follows: When (1) locking the link xy creates a directed cycle with already locked links or when (2) some link zy has already been locked, then we skip xy . Otherwise we lock xy .

In example 14, we lock $d \rightarrow e$ with a strength of (63,34). We then lock $f \rightarrow a$ with a strength of (62,35). We then skip ae with a strength of (61,36), since there is already a locked link ze . We then skip be with a strength of (60,37), since there is already a locked link ze . We then lock $e \rightarrow f$ with a strength of (59,38). We then skip fd with a strength of (58,39), since locking fd would create a directed cycle with the already locked links $d \rightarrow e$ and $e \rightarrow f$. We then lock $d \rightarrow b$ with a strength of (57,40). We then lock $b \rightarrow c$ with a strength of (56,41). We then skip ec with a strength of (55,42), since there is already a locked link zc . We then skip da with a strength of (54,43), since there is already a locked link za . We then skip ca with a strength of (53,44), since there is already a locked link za . We then skip ab with a strength of (52,45), since there is already a locked link zb . We then skip cd with a strength of (51,46), since locking cd would create a directed cycle with the already locked links $d \rightarrow b$ and $b \rightarrow c$. We then skip fb with a strength of (50,47), since there is already a locked link zb . We then skip cf with a strength of (49,48), since there is already a locked link zf .

The winner of Heitzig’s river method is alternative d because there is no alternative $y \in A \setminus \{d\}$ with $y \rightarrow d$.

Tables 11.3 and 11.4 show how frequently the Simpson-Kramer MinMax method, the Schulze method, Tideman’s ranked pairs method and Heitzig’s river method agree or disagree with each other in a random simulation. The tests for tables 11.3 and 11.4 are created as follows:

1. At first, for each pair of alternatives $ij \in A$, we decide whether alternative i pairwise beats alternative j or alternative j pairwise beats alternative i .

To make sure that all alternatives are in the Smith set, we demand that alternative i pairwise beats alternative $i+1$ for every $i = 1, \dots, (C-1)$. Furthermore, we demand that alternative C pairwise beats alternative 1.

For the remaining pairs of alternatives $ij \in A$, we decide randomly whether alternative i pairwise beats alternative j or alternative j pairwise beats alternative i .

2. Then, the strengths of the $(C \cdot (C-1))/2$ pairwise wins are ordered randomly. This is sufficient because the winners of the Schulze method, the ranked pairs method and the Simpson-Kramer MinMax method depend only on the order of the strengths of the pairwise wins, not on their absolute strengths. This is equivalent to saying that the number of voters goes to infinity.

As there are no wins with equivalent strengths, the Simpson-Kramer MinMax method, the Schulze method, Tideman’s ranked pairs method and Heitzig’s river method always have unique winners. Therefore, there is no need to specify how to handle indecisive cases.

The columns in table 11.3 are:

Column “A”: number of alternatives. For each number in column “A”, 1,000,000 tests were run.

Column “B”: number of tests where ...

- the Simpson-Kramer MinMax method chooses alternative $a_1 \in A$,
- the Schulze method chooses alternative a_1 ,
- Tideman’s ranked pairs method chooses alternative a_1 ,
- Heitzig’s river method chooses alternative a_1 .

Column “C”: number of tests where ...

- the Simpson-Kramer MinMax method chooses alternative $a_1 \in A$,
- the Schulze method chooses alternative a_1 ,
- Tideman’s ranked pairs method chooses alternative a_1 ,
- Heitzig’s river method chooses alternative $a_2 \in A \setminus \{a_1\}$.

Column “D”: number of tests where ...

- the Simpson-Kramer MinMax method chooses alternative $a_1 \in A$,
- the Schulze method chooses alternative a_1 ,
- Tideman’s ranked pairs method chooses alternative $a_2 \in A \setminus \{a_1\}$,
- Heitzig’s river method chooses alternative a_1 .

Column “E”: number of tests where ...

- the Simpson-Kramer MinMax method chooses alternative $a_1 \in A$,
- the Schulze method chooses alternative a_1 ,
- Tideman’s ranked pairs method chooses alternative $a_2 \in A \setminus \{a_1\}$,
- Heitzig’s river method chooses alternative a_2 .

Column “F”: number of tests where ...

- the Simpson-Kramer MinMax method chooses alternative $a_1 \in A$,
- the Schulze method chooses alternative a_1 ,
- Tideman’s ranked pairs method chooses alternative $a_2 \in A \setminus \{a_1\}$,
- Heitzig’s river method chooses alternative $a_3 \in A \setminus \{a_1, a_2\}$.

Column “G”: number of tests where ...

- the Simpson-Kramer MinMax method chooses alternative $a_1 \in A$,
- the Schulze method chooses alternative $a_2 \in A \setminus \{a_1\}$,
- Tideman’s ranked pairs method chooses alternative a_1 ,
- Heitzig’s river method chooses alternative a_1 .

Column “H”: number of tests where ...

- the Simpson-Kramer MinMax method chooses alternative $a_1 \in A$,
- the Schulze method chooses alternative $a_2 \in A \setminus \{a_1\}$,
- Tideman’s ranked pairs method chooses alternative a_1 ,
- Heitzig’s river method chooses alternative a_2 .

Column “I”: number of tests where ...

- the Simpson-Kramer MinMax method chooses alternative $a_1 \in A$,
- the Schulze method chooses alternative $a_2 \in A \setminus \{a_1\}$,
- Tideman’s ranked pairs method chooses alternative a_1 ,
- Heitzig’s river method chooses alternative $a_3 \in A \setminus \{a_1, a_2\}$.

Column “J”: number of tests where ...

- the Simpson-Kramer MinMax method chooses alternative $a_1 \in A$,
- the Schulze method chooses alternative $a_2 \in A \setminus \{a_1\}$,
- Tideman’s ranked pairs method chooses alternative a_2 ,
- Heitzig’s river method chooses alternative a_1 .

Column “K”: number of tests where ...

- the Simpson-Kramer MinMax method chooses alternative $a_1 \in A$,
- the Schulze method chooses alternative $a_2 \in A \setminus \{a_1\}$,
- Tideman’s ranked pairs method chooses alternative a_2 ,
- Heitzig’s river method chooses alternative a_2 .

Column “L”: number of tests where ...

- the Simpson-Kramer MinMax method chooses alternative $a_1 \in A$,
- the Schulze method chooses alternative $a_2 \in A \setminus \{a_1\}$,
- Tideman’s ranked pairs method chooses alternative a_2 ,
- Heitzig’s river method chooses alternative $a_3 \in A \setminus \{a_1, a_2\}$.

Column “M”: number of tests where ...

- the Simpson-Kramer MinMax method chooses alternative $a_1 \in A$,
- the Schulze method chooses alternative $a_2 \in A \setminus \{a_1\}$,
- Tideman’s ranked pairs method chooses alternative $a_3 \in A \setminus \{a_1, a_2\}$,
- Heitzig’s river method chooses alternative a_1 .

Column “N”: number of tests where ...

- the Simpson-Kramer MinMax method chooses alternative $a_1 \in A$,
- the Schulze method chooses alternative $a_2 \in A \setminus \{a_1\}$,
- Tideman’s ranked pairs method chooses alternative $a_3 \in A \setminus \{a_1, a_2\}$,
- Heitzig’s river method chooses alternative a_2 .

Column “O”: number of tests where ...

- the Simpson-Kramer MinMax method chooses alternative $a_1 \in A$,
- the Schulze method chooses alternative $a_2 \in A \setminus \{a_1\}$,
- Tideman’s ranked pairs method chooses alternative $a_3 \in A \setminus \{a_1, a_2\}$,
- Heitzig’s river method chooses alternative a_3 .

Column “P”: number of tests where ...

- the Simpson-Kramer MinMax method chooses alternative $a_1 \in A$,
- the Schulze method chooses alternative $a_2 \in A \setminus \{a_1\}$,
- Tideman’s ranked pairs method chooses alternative $a_3 \in A \setminus \{a_1, a_2\}$,
- Heitzig’s river method chooses alternative $a_4 \in A \setminus \{a_1, a_2, a_3\}$.

The standard deviation is in brackets. When there are *pos* positive tests and *neg* negative tests, then the standard deviation is:

$$\sqrt{((pos \cdot neg) / (pos + neg))}.$$

A	B	C	D	E	F	G	H

Table 11.3 (part 8 of 8): comparison of the Simpson-Kramer MinMax method, the Schulze method, Tideman’s ranked pairs method and Heitzig’s river method (source: own calculation)

With table 11.3, it is possible to calculate how frequently the different election methods agree with each other. The columns in table 11.4 are:

Column “Q” ($= \text{“B”} + \text{“C”} + \text{“D”} + \text{“E”} + \text{“F”}$): number of tests, where the Simpson-Kramer MinMax method and the Schulze method choose the same alternative.

Column “R” ($= \text{“B”} + \text{“C”} + \text{“G”} + \text{“H”} + \text{“I”}$): number of tests, where the Simpson-Kramer MinMax method and Tideman’s ranked pairs method choose the same alternative.

Column “S” ($= \text{“B”} + \text{“D”} + \text{“G”} + \text{“J”} + \text{“M”}$): number of tests, where the Simpson-Kramer MinMax method and Heitzig’s river method choose the same alternative.

Column “T” ($= \text{“B”} + \text{“C”} + \text{“J”} + \text{“K”} + \text{“L”}$): number of tests, where the Schulze method and Tideman’s ranked pairs method choose the same alternative.

Column “U” ($= \text{“B”} + \text{“D”} + \text{“H”} + \text{“K”} + \text{“N”}$): number of tests, where the Schulze method and Heitzig’s river method choose the same alternative.

Column “V” ($= \text{“B”} + \text{“E”} + \text{“G”} + \text{“K”} + \text{“O”}$): number of tests, where Tideman’s ranked pairs method and Heitzig’s river method choose the same alternative.

200	995,522 (±67)	72,953 (±260)	161,585 (±368)	73,206 (±260)	162,156 (±369)	79,624 (±271)

Table 11.4 (part 4 of 4): comparison of the Simpson-Kramer MinMax method, the Schulze method, Tideman’s ranked pairs method and Heitzig’s river method (source: own calculation)

Table 11.4 shows that, when the number of alternatives increases (column “A”), the probability that the Schulze method confirms with the Simpson-Kramer MinMax method goes to certainty (column “Q”) while, for every other pair of election methods, the probability that they agree with each other goes to zero. For every number of alternatives, the probability that the Schulze method confirms with the Simpson-Kramer MinMax method is above 90%. This demonstrates that (unlike Tideman’s ranked pairs method and Heitzig’s river method) the Schulze method doesn’t only satisfy the Smith criterion, reversal symmetry and independence of clones; it also gives a justification why the Schulze winner is a desirable alternative.

Acknowledgments

I want to thank Lowell Bruce Anderson, Ratip Emin Berker, Blake Cretney, James Green-Armytage, Jobst Heitzig, Ross Hyman, Aleksei Kondratev, Rob Lanphier, Rob LeGrand, Andrew Myers, Norman Petry, Nic Tideman, Kevin Venzke, Douglas R. Woodall, and Thomas Zavist for fruitful discussions.

Appendix: Proposed Statutory Rules for the Schulze Single-Winner Election Method with Margins

Article 1 [Preferential Ballot]

Each ballot shall contain a complete list of all qualified candidates. Furthermore, each voter may write in *{number of write-in options}* additional candidates. Each voter ranks these candidates in order of preference. The individual voter may give the same preference to more than one candidate, he may keep candidates unranked, and he may skip numbers. When a given voter does not rank all candidates, then it is presumed that this voter strictly prefers all ranked candidates to all not ranked candidates and that this voter is indifferent between all not ranked candidates.

Article 2 [Schulze Method]

§1: Suppose $N[x,y]$ with $x \neq y$ is the number of valid ballots on which candidate x is preferred to candidate y . For all pairs of candidates x and y with $x \neq y$, $N[x,y]$ shall be calculated.

§2: A “path from candidate x to candidate y ” with $x \neq y$ is a sequence of candidates $c(1), \dots, c(n)$ that starts with $x = c(1)$ and ends with $y = c(n)$ and that visits the same candidate not more than once. That means: If $i \neq j$, then $c(i) \neq c(j)$.

§3: The “strength” of the path $c(1), \dots, c(n)$ is the minimum of $N[c(i), c(i+1)] - N[c(i+1), c(i)]$ for all $i = 1, \dots, (n-1)$.

§4: $P[a,b]$ with $a \neq b$ is the maximum value such that there is a path from candidate a to candidate b with this strength.

§5: For all pairs of candidates d and e with $d \neq e$, $P[d,e]$ shall be calculated. Candidate f is a “potential winner” if and only if $P[f,g] \geq P[g,f]$ for every other candidate g .

Article 3 [Tie-Breaking]

§1: When there is only one potential winner, then he is the final winner.

§2: When there is more than one potential winner, then we pick a random ballot. All those potential winners b for whom there is another potential winner a such that candidate a is preferred to candidate b on this randomly chosen ballot lose their status of being a potential winner.

§3: We continue picking ballots randomly from those that have not yet been picked and use them to reduce the set of potential winners, as described in §2.

§4: When all ballots have been picked and there is still more than one potential winner, then the final winner is chosen randomly from these potential winners.

Article 4 [Example]

§1: There are 4 candidates and 21 voters.

8 voters prefer a to c to d to b .
 2 voters prefer b to a to d to c .
 4 voters prefer c to d to b to a .
 4 voters prefer d to b to a to c .
 3 voters prefer d to c to b to a .

§2: The pairwise matrix N looks as follows:

	$N[*,a]$	$N[*,b]$	$N[*,c]$	$N[*,d]$
$N[a,*]$	---	8	14	10
$N[b,*]$	13	---	6	2
$N[c,*]$	7	15	---	12
$N[d,*]$	11	19	9	---

§3: The pairwise matrix can also be written as a graph. The strength of the link from candidate i to candidate j is $N[i,j] - N[j,i]$.

§4: The corresponding graph looks as follows:

§5: The strongest path ...

- ... from candidate a to candidate b is $a \xrightarrow{7} c \xrightarrow{9} b$ with a strength of $P[a,b] = 7$.
- ... from candidate a to candidate c is $a \xrightarrow{7} c$ with a strength of $P[a,c] = 7$.
- ... from candidate a to candidate d is $a \xrightarrow{7} c \xrightarrow{3} d$ with a strength of $P[a,d] = 3$.
- ... from candidate b to candidate a is $b \xrightarrow{5} a$ with a strength of $P[b,a] = 5$.
- ... from candidate b to candidate c is $b \xrightarrow{5} a \xrightarrow{7} c$ with a strength of $P[b,c] = 5$.
- ... from candidate b to candidate d is $b \xrightarrow{5} a \xrightarrow{7} c \xrightarrow{3} d$ with a strength of $P[b,d] = 3$.
- ... from candidate c to candidate a is $c \xrightarrow{9} b \xrightarrow{5} a$ with a strength of $P[c,a] = 5$.
- ... from candidate c to candidate b is $c \xrightarrow{9} b$ with a strength of $P[c,b] = 9$.
- ... from candidate c to candidate d is $c \xrightarrow{3} d$ with a strength of $P[c,d] = 3$.
- ... from candidate d to candidate a is $d \xrightarrow{17} b \xrightarrow{5} a$ with a strength of $P[d,a] = 5$.
- ... from candidate d to candidate b is $d \xrightarrow{17} b$ with a strength of $P[d,b] = 17$.
- ... from candidate d to candidate c is $d \xrightarrow{17} b \xrightarrow{5} a \xrightarrow{7} c$ with a strength of $P[d,c] = 5$.

§6: The unique potential winner is candidate d because, for every other candidate x , we have $P[d,x] \geq P[x,d]$.
